We observe, then, that the acme in number as well as in activity of the leukocytes in pneumonia appears to bear such relation to the crisis that it is logical to assume that they are directly concerned in its production.

THE ANTIBODIES IN PNEUMONIA

Crisis in most cases of pneumonia occurs between the fifth and tenth days of the attack, which usually is held to begin with the chill. Undoubtedly, the infection actually begins a little earlier. Whenever substances calling forth specific antibodies are introduced into the body in moderate quantities, it requires a few days before the antibodies accumulate in any considerable amount in the blood, the high points being reached about the tenth or twelfth day, so that the time when the *crisis occurs corresponds closely to the high point of the antibody curve in general.*

Let us now briefly review what is known of antibody formation in pneumonia in order to learn what relation this may bear to crisis.

Using a readily phagocytable pneumococcus, Wolf[15] found that in typical pneumonia the specific opsonin as measured by means of the opsonic index is subnormal in amount at first, but rises above normal as the crisis is passed, reaching its height soon afterward, whereupon there seems to be a speedy return to normal. In fatal cases the index may drop lower and lower. Boettcher[16] also found that as a rule the opsonic power of the serum was higher the nearer the crisis.

Testing the combined effect on pneumococci of serum and leukocytes by means of the plate method, Eggers[17] *determined that in most cases of lobar pneumonia the* antipneumococcal, that is, the opsonic, power of the serum increases, *being as a rule greatest at or just after* the onset of crisis and lasting a variable period afterward. In the cases in which this increase did not occur the course was irregular or the termination fatal.

Still others have made observations to the same general effect; but as increase in opsonin was demonstrable with respect only to non-virulent or feebly virulent pneumococci, highly virulent pneumococci such as are present in the blood in pneumonia apparently not being affected by the serum at all, doubt was expressed whether the results of the estimation of opsonin really were as *significant as they at first sight would appear to be.*[18] *It was urged that if phagocytosis plays a decisive rôle in the cure of pneumonia, then surely pneumonic serum* would be actively opsonic for virulent pneumococci. Just recently it has been found that this is so. The trouble with the early experiments seems to have been that the tests were not made with the pneumococcus infecting the patient whose serum was used, as Clough[19] finds that soon after crisis as well as during lysis the pneumonic serum may be actively opsonic for the homologous organism in a highly virulent state, and such *activity may be limited quite strictly to the homologous* strain, illustrating well the peculiar group limitations of the antipneumococcal reactions.

The most striking evidence, however, of the increase in the antipneumococcal power in recovery from pneumonia is furnished by the action of the serum in protecting animals against homologous pneumococci of extreme virulence.[20] We now have the results of several series of faultless experiments showing that there is a definite clean-cut rise in the protective power of the serum coincident with crisis and observable also during lysis. From 0.001 to 0.2 c.c. of postcritical serum may protect against a thousand—yes, even a million—times the single fatal dose of homologous pneumococci, but even so highly potent a serum quickly reaches the limit below which its protection is ineffective. A certain amount of antisubstances in proportion to the weight of the animal is essential, and Neufeld[20] suggests that in pneumonia the antibodies formed remain powerless until they reach this necessary concentration, whereupon the pneumococci are destroyed quickly by the phagocytes, and crisis results. The protective action of pneumonic serum is due to the same antisubstances as in the serum of immunized animals, namely, substances that promote phagocytosis, and Clough found that the protective power strictly parallels the power to render virulent pneumococci phagocytable.

[14] Here it may be noted too that Hiss and Zinsser (Jour. Med. Research, 1908, xix, 322), found that extracts of leukocytes of immune animals seemed to possess greater curative powers than extracts of leukocytes of normal animals. Concerning increased phagocytic activity of leukocytes in acute infectious diseases see also Schaefer-Hieber (Deutsch. Arch. f. klin. Med., 1913, cxii, 14).

Another important change in the serum at the time of crisis is the development of the power to digest pneumococcus proteins described by Dick.[21] The serum now contains substances that split up these proteins, producing digestive products which are easily detected by means of appropriate tests. Rosenow[22] has shown that the serum of immune animals has an increased proteolytic power with respect to pneumococcus proteins, and the results of his experiments indicate that recovery from pneumococcus infection is associated with the breaking up of cleavage products of pneumococci beyond toxic stage at which such products are toxic.

According to the work of Vaughan,[23] protein digestive products may cause many of the general symptoms present in pneumonia, including the fever. The intensification of the symptoms as crisis occurs, as well as the symptoms peculiar to the crisis itself, may perhaps be caused by the large quantity of protein poisons set free at this time and rapidly broken up into non-toxic products.[24]

We reach the important conclusion that the crisis coincides with the height of a wave-like increase of antipneumococcal substances in the blood. We find that such is the case as the result of various tests and measurements, of which most weight must be given to the demonstration of the protective and opsonic action of postcritical serum with respect to its homologous virulent pneumococcus.

An increase in antipneumococcal substances occurs also in cases in which recovery occurs by lysis, but in cases that proceed rapidly to a fatal ending no such increase in free antisubstances seems to be demonstrable.

SUMMARY

The cure of pneumonia results from the destruction of the pneumococci in the lungs and in the blood. This is accomplished by phagocytosis and also by extracellular digestive processes.

The predominating general defensive reactions in pneumonia are leukocytosis and the production of antibodies for pneumococci, of which the opsonins are best known; and these appear to be specific for the group to which the infecting pneumococcus belongs.

In rapidly fatal cases the defensive reactions are inadequate to destroy the pneumococci which persist and multiply in the lungs and in the blood, and free antibodies have not been demonstrated in the blood.

In favorable cases the pneumococci are destroyed more or less rapidly when the antipneumococcal reactions reach a certain height. We may assume that lysis results when the destruction takes place more gradually. Crisis is the effect of prompt destruction. In both cases, but demonstrated more clearly in crisis, there is an excess of free antibodies in the blood.

THE TREATMENT OF THE PNEUMONIAS *

ROBERT N. WILLSON, M.D.
PHILADELPHIA

In a study of the treatment of pneumonia it will be well at the outset to remind ourselves of the meaning of the term. Not all writers and not all clinicians mean by pneumonia merely the blood infection which localizes its lesions in the lung in the form of lobar or fibrinous pneumonia. A few remember the fact that there are many types of infection other than that of the pneumococcus capable of producing the picture of lobar pneumonia. Still fewer recall the ever-increasing frequency of what we may term, for sake of accuracy of description, bronchocatarrhal pneumonia. The very few who do indeed make these discriminations avoid speaking of the "treatment of pneumonia," and are never found including under the one term conditions as different as darkness from light.

PNEUMONIA IN THE MEDICAL WARDS OF THE PHILADELPHIA GENERAL HOSPITAL, 1911-1913

Total number of cases*	596
Total number of recoveries	232
Total number of deaths	364
Total percentage of recoveries (varying from 0 to 53 per cent.) on the various medical services (representing the various methods of treatment)	38.5
Total percentage of deaths (varying from 100 to 47 per cent.)	61.5
Number of cases which ran a low, irregular febrile course (not over 100 F.; often subnormal or normal throughout), with rapid pulse	393
Number of cases typically and constantly febrile (above 100 F.), and frankly suggestive of croupous pneumonia	203

* This total does not include the pneumonia cases in the Children's Hospital or those in the surgical wards, nor does it deal with cases of so-called hypostatic pneumonia. Practically every case in the series was treated in cold fresh air, very many of the patients having been placed outdoors on the bridges constructed for the purpose. Perhaps the majority of the cases occurred in alcoholic subjects; not a few were in the course of acute alcoholism.

Without dwelling on the fact that either fibrinous or bronchocatarrhal pneumonia may be caused by any one or more than one (a mixed infection) of the common infecting organisms, I wish simply to point to the need of determining very early just which form of involvement the physician has in hand. The chart of temperature, pulse, and respiration usually goes far toward making the differentiation. The history of the case, especially the former state of vigor and health, will just as frequently furnish the needed suggestion. As a rule, the physical examination, not of the lungs, but of the whole patient, will make the diagnosis certain; and, as the outcome of the case may easily be dependent on just this certainty, it behooves us to lay hold on it and avoid having to face the correct diagnosis at the necropsy-table, or a little later still, when the lung tissue is placed under the microscope.

[23] Vaughan: Protein Split Products in Relation to Immunity and Disease, 1913.

[24] At this point it is of interest to note the explanation of crisis advanced by Frank (De Curandi Hominum Morbis, Epitome, etc., 1810), one hundred years ago: "If the matter of the disease be expelled by some one convenient outlet, in the skin, kidneys, pulse or blood-vessels, the crisis is simple; if by several of these at the same time it is compound; if the whole be carried off at once it is perfect. If it be carried off at different times it is a lysis, or resolution."

* Read before the Philadelphia County Medical Society, Nov. 12, 1913.

In the first place, by lobar or fibrinous *pneumonia* I think that we all mean the clinical picture that opens suddenly, often in a vigorous, healthy person (though many times in a tired, overfed one), with a chill, vomiting, an aching back and a high temperature. The pathologic stages customarily run are congestion, red hepatization, gray hepatization and finally resolution, or some catastrophe. The clinical picture comprises a high constant temperature, a full, fairly slow hypertension pulse, an overworking but strong heart, a progression from the signs of congestion to those of consolidation of one or more lobes of the lung, rusty sputum and a febrile course of from seven to nine days, terminated by crisis, with recovery in approximately 75 per cent. of instances.

Over against this picture there is another equally clean-cut and striking — that of bronchocatarrhal pneumonia. The patient is usually an asthenic person before and after the onset of the infection. With few exceptions, perhaps none, he or she has a definite bronchitis at the time of, and probably directly causative of, the onset. Certain diseases, always characterized by a bronchitis, present a definite tendency to complication by bronchocatarrhal pulmonary involvement. Among these are measles, whooping-cough, small-pox, influenza, typhoid fever and gout, or the irritation of the bronchial tree due to food poisoning which masquerades under that name. It is my belief that more "colds" and bronchocatarrhal pneumonias are to be traced to a gastro-intestinal origin and possibly to a colon bacillus infection than to any other one cause.

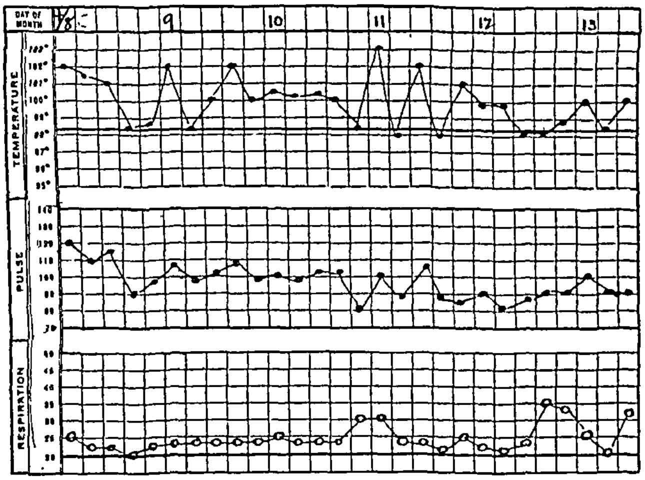

Chart 1.—Ordinary instance and customary appearance of chart in bronchocatarrhal pneumonia.

The pathologic picture is invariably one of bronchitis, terminal bronchiolitis, pneumonitis by *extension from* the bronchioles, and frequently a tendency for the adjacent foci of consolidation to run together and to involve considerable areas of lung tissue. It would seem as though all that were necessary for the development of the picture were an asthenic person, a bronchitis, and a lung the inherent vitality of whose tissues (along with all the other tissues in the body) is lowered beyond the point of successful resistance to infection and inflammation.

The clinical course is one of low, irregular temperature (sometimes subnormal throughout), usually a weak, rapid, running pulse, a respiratory rate not far above the normal line, often bloody (even rusty) sputum, a course lasting from two days to many weeks, and termination by crisis in many brief cases, but far more frequently by lysis in the customary long-drawn-out type. If the case reaches the necropsy-table it may or may not present a lung solid throughout from the coalescence of many small areas of peribronchiolar consolidation.

With equal or even greater frequency we note in the low-grade pneumonias the involvement of favorite seats of predilection. Such are the middle lobe on the right side, especially near the anterior axillary line, the areas beneath the inner angle of one or other scapula, and less frequently the one or the other pulmonary base or apex. In children usually the apex is chosen, and in them very frequently the exudate is in the main epithelial, is free from fibrin, and indicates the bronchocatarrhal type of infection.

In the foregoing contrast there are at once evident two main considerations: First, the need to remember that in the lobar or fibrinous type of pneumonia we are dealing, at least in the beginning, with a formerly, and often still, vigorous patient; while in pneumonitis of the bronchocatarrhal type we invariably encounter an asthenic, deeply toxic state in which the conservation of the vital forces is the main objective, and in which in infancy, adult years or old age, the patient will die unless these are jealously conserved. In many, if not in most respects, the treatment of the two conditions is the same. In certain essential points, however, the methods of handling must be as divergent as two opposite-traveling roads. It is because of this fact that I am emphasizing the existence of the two distinct types of pneumonia, and directing attention to the life-saving character of certain measures in the one, and their death-dealing influence in the other.

FRESH AIR

In both forms of pneumonia an abundance of fresh air is an essential. In health, the main function of the air-vesicles, which, if spread out, would cover many square feet of flat surface, is to supply oxygen to the red corpuscles of the circulating blood. For this purpose every vesicle must or should receive its full quota of pure, fresh air. The destination of the oxygen is primarily the heart; thence to the body-tissues from the crown to the toe. We have no cardiac tonic or stimulant that compares in efficiency with oxygen. In clean fresh air it is supplied in Nature's chosen proportions and in her own way. An ample supply is even more essential to the pneumonia patient, very many of whose air-vesicles are full of blood or of exudate, and out of commission as oxygen collectors and distributors. In addition, the blood is often incapable of carrying its wonted supply. The body and especially the heart need, as never before, the nourishing and stimulating influence of the oxygen from fresh air. The lungs are able to supply only a portion of the usual amount, often only a very small portion. It becomes, therefore, more and more important that all of the supply shall be pure, and unmixed with harmful ingredients. Hence the adoption of the treatment in the fresh air.

If possible, the patient should be placed bodily outdoors, *provided, and only provided, that the case is of a febrile type of fibrinous pneumonia.* I think it safe to say that exceedingly few, if any, instances are to be found of genuine fibrinous pneumonia in which the temperature curve averages as low as 100 F. I have not observed one. It will be safe, therefore, in fibrinous pneumonia to give free rein to the use of the fresh-air treatment, cold when possible, warm when there is no other supply. Such a patient literally cannot "take cold." He can, however, be made uncomfortable in extreme weather, and should be protected by a mackintosh placed over the mattress, and by bedclothes which surround the body, and do not simply lie on it. At the foot of the bed the blankets and bed-linen should be folded up under the feet and legs, forming a kind of sleeping-bag. Hot-water bags or bricks should be applied to the feet, if these precautions fail to make them comfortable. Only the nose and mouth need to be exposed to the cold fresh air in order to insure as ample as possible a supply to the embarrassed and hungry air-vesicles and to the red corpuscles waiting for their oxygen-supply.

The patient with bronchocatarrhal pneumonitis needs the fresh air and the oxygen as seriously as does he with the fibrinous inflammation and exudate. If supplied in the form of cold air, however, to a body whose poverty in heat and vital energy is already so low that it cannot show a temperature reaction to the influence of the toxin, the result will be the opposite of that desired, and death may be the result. I do not refer only to children and to the senile, but to the patient of any age. I have, indeed, seen an old woman hurried to her end by the misguided enthusiasm of an intern, who had recently read an article of the type just now in vogue, recommending the "cold-fresh-air treatment for pneumonia," and neglecting to discriminate between the types of infection and of involvement of the lung.

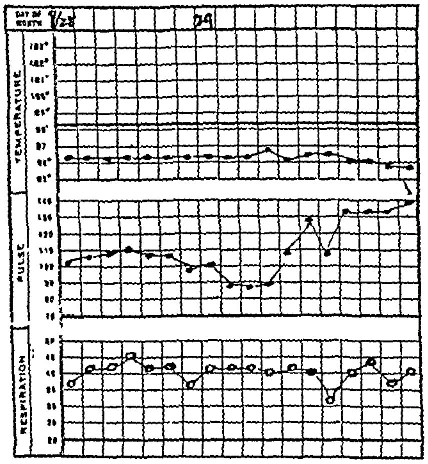

Chart 2.—Fatal case of bronchopneumonia. Base of right lung involved. Marked tubular breath-sounds, large moist râles. Chill, cough, herpes, septic tongue, severe dyspnea.

It would be comparatively safe to entrust the decision between the application of cold and warm fresh air to the patient, who, in his or her choice, would practically make the diagnosis of the nature of the pneumonia. Suffice it to say that he who treats the average case of bronchocatarrhal pneumonia by the application of cold fresh air will of necessity in so doing elect to shoulder the responsibility for many an unnecessary death and for elevating the mortality of a disease whose lethal influence reaches a sufficiently high mark without assistance in that direction from the physician and nurse.

The reason is not far to seek. Examine on the necropsy-table the mucous membranes of the air-passages in a fatal case of the so-called low-grade pneumonia. From the mouth to the finest bronchioles the surface is deeply congested and inflamed and purplish or reddish-blue. Passing a current of cold air over such a surface during and in each inspiration is like refrigerating the heart's blood immediately before its supply. In addition, it actually gives pain. The application of cold air to the body of the devitalized patient who cannot be kept warm is an influence that will most certainly in many instances send him or her over the boundary between life and death that might not have been crossed, under other circumstances, until a much later day. Especially in instances of gouty bronchitis and gouty pneumonia I have studied a number of patients who seemed to retrograde with the windows open, and breathed with ease and ceased coughing the moment they were closed.

In a suitable, febrile, sthenic case of fibrinous pneumonia the respiration becomes easier, the heart-action less labored, sleep comes with less effort, and food is taken with some relish when the patient is moved even from the well-aired room to the outdoor air. Both the cerebral symptoms (delirium) and the occasional distressing intestinal paresis seem less likely to occur and more easily controlled under the outdoor regimen.

Try the same method on the asthenic patient with bronchocatarrhal pneumonia, and the pallor and cyanosis will increase instead of diminishing, the cough and expectoration will be aggravated, and the heart, which is already carrying more than it can tolerate in the way of a load, receives a new burden and the heaviest of all in the way of an added embarrassment from stasis in the lung.

When we speak of the fresh-air treatment of pneumonia, therefore, let us take pains to mention the fact to those who are eager to learn that fresh air can be furnished either cold or warm, and that, in possibly the majority of instances (bronchocatarrhal pneumonia being the more frequent type), the application of cold fresh air will certainly do harm.

FOOD

Over and above oxygen in the form of fresh air, the regulation of the food-supply forms an important item in the treatment of both types of pneumonia. In the fibrinous inflammation, with its short duration, probably the entire seven or nine days might be experienced by a well-nourished patient with no food intake whatsoever, and the outcome of the disease be more surely favorable as a consequence. There are few persons who have the moral courage to map out such a regimen. For the comfort of the family, if for nothing else, in private practice food must be administered. It becomes an object, however, to use as little as possible of the most nourishing and easily digestible form of food, at as *infrequent intervals as the exigencies of the case permit.* Milk forms the ideal diet, so long as tympanites remains absent. This one staple may be supplemented or replaced by simple soft foods such as junket, custard, one-minute boiled eggs and soft milk-toast. Occasionally a pneumonia patient is hungry throughout the course of the disease. Such a patient should be fed more liberally, though with judgment, until the convalescence calls for an ample supply of food.

In the bronchocatarrhal pneumonias the patient requires from the first a supporting diet, though not a grain over and above that which is actually needed for the body requirements, nor more than can be thoroughly digested by a poisoned gastro-intestinal mechanism in a deeply toxic economy. The course is likely to be a longer one than in true fibrinous pneumonia, and provision must accordingly be made for a sustained resistance to a long insidious attack. It has been my custom in the last few years to feed a patient with bronchocatarrhal pneumonia along lines very similar to the ones employed in typhoid fever. I do not favor restriction to a milk or liquid dietary. On the contrary, I have found it helpful to prescribe approximately 2 quarts of milk in the twenty-four hours, and in addition, three times during the day, a one-minute boiled egg and some agreeable addition, such as custard, finely chopped meat, mashed potatoes, lettuce, dry toast, or a little of any simple vegetable desired. This regimen cannot safely be followed unless the rules yet to be detailed for the housekeeping of the intestinal canal are rigidly observed. With proper care, however, one will witness many a patient who enters on this disease thin and haggard and worn, emerging from it in a far better state of nourishment, and ready to enter on a real and soon a complete convalescence.

WATER

Another essential in the treatment of the pneumonias is an adequate supply of drinking-water. If sufficient is ingested from the beginning of the illness there will rarely appear the so-called toxic or typhoid state in which the tongue is dry and even fissured, the skin parched, and the patient perhaps delirious or comatose. Not less than 3 pints should be taken by the average adult patient during the twenty-four hours, and the prescription for this amount (6 glasses), or better 2 quarts (8 glasses), should be placed in black and white on the treatment-sheet. This measure is as important as is the flooding of the patient with fresh air, and will assist in attaining the same ends.

THE GASTRO-INTESTINAL TRACT

I know of no measure more certain to aid in the furnishing of a favorable prognosis in both types of pneumonia than a thorough initial intestinal sweeping by means of castor oil, and the repetition of this procedure every second day throughout the course of the disease. Under this regimen, provided a sufficient supply of clean fresh air of the proper temperature be afforded, the vast majority of patients will require no other drug treatment from start to finish. No other laxative will do the work accomplished by castor oil. I know of none that can be used with so little fear of harm. It can be given in flavored powder form (rubbed up with heavy magnesia) suspended in milk; or if necessary can be passed directly into the stomach through a fine nasal tube, the outside of which has been touched with a weakly mentholated oil. Some patients take with ease the necessary dozen flexible capsules.

I have become more and more thoroughly convinced that the great number of bronchitides find their origin in toxemias arising from the intestinal tract. Too much food, articles of food ill suited to the individual, and retention of decomposition and fermentation products in the intestinal tube from whatever source, are the causes of many "colds" and inflammations of the respiratory passages which are attributed, as a rule, to drafts, outdoor exposure, and to every other cause except the real one. Unless the process has gone too far, the symptoms begin to subside when the gastro-intestinal tract is swept and kept clean, and the offending substances (perhaps only a particle in some kink or coil of the bowel) have been removed, and when the stock and store of toxin already accumulated in the body have been lowered below the symptom-producing line. This may not be accomplished by the first purgation. Very often, however, the influence on the patient is little short of wonderful, and the whole course of the disease a different one thereafter. It is remarkable how reluctant many physicians and many laymen appear to be to empty the bowel from end to end as the initial procedure in the treatment.

Especially difficult does this lesson appear for the hospital intern. "The bowels have already moved," we are told by the doctor and layman alike, when all that has been "moved" has been the lowest rectal 6 or 8 inches, or at most the sigmoid flexure, of the intestinal tube. Other laxatives than castor oil may be used, and any one is better than none. It is well, however, to avoid those that tend to irritate kidneys that are already suffering from the same bacteriemia and toxemia that has affected the lung. Mercurials fall within this class, even calomel furnishing more of risk than of gain. Phenolphthalein has within the recent past been shown to produce albuminuria even in healthy persons. Probably magnesium citrate, next to castor oil, offers the most satisfactory means of emptying the intestinal canal with the least likelihood of damage to other structures during its elimination.

Occasionally in the middle of a pneumonia of either type, especially in the course of a surgical (ether or shock) bronchocatarrhal process, the stomach will appear paretic, and balloon with gas. At such times lavage through the stomach-tube will, as a rule, give immediate relief from both the distention and the attendant vomiting. More frequently tympanites forms a constant feature of a deeply toxic case. In such patients the high rectal tube, high asafetida enemas or suppositories, or turpentine and soapsuds enemas, will form a few of the measures that may be instituted for the relief of meteorism. Hot water or turpentine stupes may also be applied to the abdomen and will often prove more effective than the internal procedures.

Peritonitis occasionally projects itself into the midst of a pneumonic picture. It is always a serious complication and may call for surgical interference.

Far more frequently there is present the picture of an appendicitis, or of a peritonitis localized elsewhere than over the appendix, which promptly disappears with the improvement in the local pulmonary and pleural condition. Even a left-sided apical pneumonia may cause rigidity and pain in the right iliac fossa. As a consequence, it will behoove the physician and surgeon to go very slowly in the use of surgical measures. I well remember two cases, the first of a medical student, carefully studied by well-known consultants who clearly recognized the presence of both pulmonary and abdominal signs. They decided against abdominal surgery, and the patient died of suppurative peritonitis. A second case I saw with Dr. M. G. Warmuth, and decided that there was reason to operate, though a right basal pneumonia was plain. Yet the abdomen was found free from trouble, and the patient had his crisis and began his convalescence the day following the operation.

MECHANICAL AND LOCAL MEASURES

Among the non-medicinal measures valuable in the treatment of the pneumonias, as well as of all toxic states, one of the most important is the care of the skin. As far as possible this should be left free to perform its functions of elimination and respiration. It should not be hampered by ointments, by poultices or by unnecessary coverings of any kind. Yet quite recently, in consultation with a fellow practitioner who had just taken charge of the case, I saw a little child, whose family would not permit the removal of a jacket of antiphlogistin which had nearly cost the baby its life. It had been in place for twenty-eight days, since first put on the surface of the chest by the physician then in charge. The child was apparently dead, poisoned by methyl salicylate and the gases of its own skin. The removal of the death-jacket, and immersion alternately in hot and cold water, caused the first deep inspiration witnessed in many hours. It is not the fault of the antiphlogistin fallacy that the baby is strong and well to-day. The skin should be kept clean. Good nursing will insure the sponging of the body surface with hot water morning and evening, and the daily changing of the clothing worn next the skin. In febrile fibrinous pneumonia sponging at regular intervals for high temperature will often be found restful and gratifying to the patient. The temperature of the water may be high or low (hot or cold) according to the preference of the patient. The same result is accomplished by either and both as far as the lowering of bodily temperature is concerned. The hot sponge, however, is far more restful and stimulating to the heart, and may be used for its cardiac tonic influence. In bronchocatarrhal pneumonias there will be no need of sponging to reduce the temperature. Apart from cleanliness, only with a view to vitalizing the cardiac and nervous functions will the procedure be advisable or salutary. Stupes applied to the chest for brief periods (fifteen minutes or thereabouts) at regular intervals furnish an important method of applying counterirritation. In the form either of turpentine or of hot-water applications, they often relieve pain and lessen the tendency to further congestion. Especially when there is an area of pleurisy over an inflamed lung, the stupe fills a most beneficent rôle. It should not, however, be allowed to remain in place for long at a time, or to fill the rôle of a poultice and thus accomplish harm rather than advantage. A favorite method of mine is to dry cup the chest generously over the involved portions of the lung, and then to apply over the entire chest hot stupes prepared by sprinkling turpentine directly on the steaming moist flannel. The stupe is removed in fifteen minutes, the skin wiped clean, perhaps moistened with a minimal quantity of petrolatum or oil of theobroma (cocoa-butter), and covered only by the light undergarment and night-clothing until the next stupe interval.

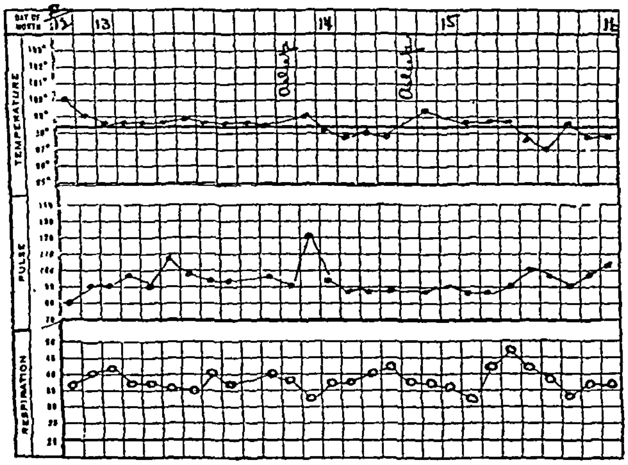

Chart 3.—Five days from the gravest stage of a fatal case of bronchocatarrhal pneumonia. Cough, dyspnea, septic tongue. Râles, tubular breath-sounds over the right lower lobe posteriorly.

I have already mentioned dry cupping, either used alone or in combination with the stupes, or, in fibrinous pneumonia, with an ice-bag. Its influence extends through many layers of chest, pleura and lung, and is one of the measures employed by our fathers which we cannot afford to lose. It is not a pleasant procedure for the patient, and hence should not be overdone. One thorough dry cupping daily will furnish all the benefit that can be obtained. More constitutes an abuse of the measure, and is one of the many forms of harmful overtreatment.

Bleeding in vigorous hypertension-cases of fibrinous pneumonia has been more in vogue than it is to-day. It is of questionable value, except when the patient is cyanotic and laboring with a dilated, distended right heart, and congestion of all the organs. Used promptly at such a time, venesection may save life, or at least remove the cause of immediate distress. No definite quantity of blood can be fixed for the termination of the bleeding. The finger should be on the pulse and the physician's eye on the patient. As soon as respiratory and cardiac relief has been afforded, the cyanosis set aside, and the patient evidently enjoying a freedom from air-hunger, the procedure should be ended, whether a pint, a quart or double the amount has been abstracted. To bleed an asthenic, bronchopneumonic patient during any stage of the disease will amount practically to robbing him of that of which he stands most in need. Venesection cannot help, and may kill him.

Hot foot-baths of mustard- or turpentine-water are often of real advantage, by way of distributing the circulation of the body, and relieving the congestion of certain areas and organs. They can be used under the bedclothing in an ordinary bed by bending the knees of the patient, and, if a modern hospital bed is used, by lowering the footpiece of the bed.

Hypodermoclysis is mentioned, only to be condemned. In all types of pneumonia the heart and the vasomotor system suffer the main burden of the attack. Under such circumstances we should spare the cardiac muscle the additional burdens of a new drug-excitant and of a new overquantity of fluid in the circulation. Occasionally in an extremely low-tension case of bronchocatarrhal pneumonia a high enteroclysis with hot sodium bicarbonate solution will furnish the much-needed warmth to the body, and if administered slowly, will be absorbed, and aid in flushing out the irritating and toxic solids from the kidneys.

I have barely mentioned the use of the ice-bag, first because I am not sure that it is ever grateful to the patient, and secondly because I feel still less assured as to its value. When cerebral symptoms are present, as of headache or delirium, an ice-cap to the head may be of service. Applied to the chest, however, I can only be sure that in fibrinous pneumonia its beneficial effect on the lung is every day coming more in question; while in the low-grade bronchocatarrhal pneumonias its very principle is as contrary to the good of the patient as is the application of cold in any form.

Occasionally in a sthenic case an irritable, overworking heart can be quieted successfully by the application of an ice-bag to the precordium, now and again over a blister.

There remains to be mentioned the evacuation of a serous or purulent pleural effusion appearing as a complication of pneumonia. Serous collections should be removed as soon as recognized, by means of the needle if the physical examination leaves the question in doubt. The puncture of the lung-tissue, provided no fluid be present, never seems to result in harm, the actual beginning of resolution frequently seeming to date from the occurrence.

Loculated or free empyemas require unobstructed drainage and call for the interference of a surgeon, under local or spinal anesthesia. Far less frequent are pericardial effusions in pneumonia. These should be treated as independent conditions, and evacuated promptly in order to enable the heart to carry its load.

NECESSITY OF CAUTION

In the use of any or all the foregoing measures one thought should stand out over and above every other in the physician's consciousness. The treatment should not be allowed to interfere with the patient's welfare or likelihood of recovery. Every measure, even the administration of food, which interferes with the patient's rest of mind and body, especially with sleep, should be interdicted as certain to yield harm. I shall never forget the look and the tone of one rare and loyal patient who, when dying from a pneumonia which had doomed her from the start, said to me, "You don't give me a moment's rest!" I learned my lesson that day, in spite of the fact that I thought her stricture oversevere; and I have never since offended on the side of overtreatment.

There should be a regular interval (not less than three hours) of rest before every new succession of treatment. The latter should be administered and completed, and again should follow the period of undisturbed rest. We can also well afford to spare the patient our own and the nurse's active interference during the night hours, except in a grave emergency. If treatment is conducted along these lines, and if these simple principles are followed, recovery should result in the vast number of pneumonias of both types, when occurring in otherwise healthy persons.

DRUG TREATMENT

As in cardiac disease, so in the pneumonias many patients would be better without than with extensive drug treatment. After the initial intestinal house-cleaning not a grain or a drop should be administered without a definite indication for so doing. Every other day the intestines must be put in order, as already outlined. If this precaution is taken, few indeed will be the cases that require any other medication from beginning to end of the disease. Danger will threaten, not so much from mechanical embarrassment of the lungs as from cardiac muscle and gangliar poisoning, from vasomotor paralysis, and *from toxemic crippling* of the nervous centers. In alcoholics the heart and nervous centers are special objects of solicitude.

I have found atropin, the most useful of a very few available drugs, both as a cardiac tonic and as a respiratory stimulant. In small doses, used hypodermically, less often by the mouth, it will steady the heart and often quiet the labored respirations.

Morphin in occasional small doses, given hypodermically, will not only quiet the cough and further sleep, but will also allay restlessness and serve as an effective cardiac sedative and tonic.

Aconite, beyond question, will quiet the overacting heart of a fibrinous pneumonia. In bronchocatarrhal pneumonia, however, it is not a safe drug to use. The already toxic heart will not suffer the application of such a powerful and treacherous cardiac depressant.

Veratrum viride serves much the same purpose, is far safer, and was a favorite drug with our fathers in medicine. They used it with a view to redistributing the circulation, especially by emptying the congested lungs and filling the abdominal vessels. Pilocarpin may be used in the presence of a strong heart to produce free sweating, and skin elimination. Strychnin, digitalis, strophanthus, and spartein, camphor, ammonia, and the calcium salts are all cardiac stimulants that may be employed when the heart begins to fly signals of distress. Too much should not be expected of any one.

Antitoxins and vaccines which promise anything in the way of real success in preventing or curing the disease have not yet been secured, probably for the reason that most pneumonias are mixed infections, and in most instances more strains than one of the main infecting organism are busily at work.

Quinin, now given in massive doses by the mouth and rectum in the form of quinin bisulphate, or hypodermically, as quinin and urea hydrochlorid, has seemed to bring miraculous results in certain hands and in certain localities. The drug has produced absolutely no effect in other sections and in other series of cases.

Expectorants seem calculated only to disorder the digestive tract; pulmonary antiseptics accomplish very much the same end. Certainly no harmless drugs known to medicine can be aimed at the disinfection of the tissues of the lung with any reasonable certainty of reaching their destination, except by local application. Creosote, creosotal, hexamethylenamin, formaldehyd inhalations, have all been suggested and employed, and have accomplished no evident benefit for the patient.

Alcohol is no longer considered a cardiac tonic, and has well-nigh lost its right to a place in a sane pharmacopeia. Just as pneumonia in the alcoholic (nearly always of the bronchocatarrhal type) is in the great majority of instances a fatal process, so the use of alcohol in the treatment of pneumonic toxemia constitutes a paradox of effort that is difficult to understand on any other ground than one of ignorance. Alcohol is a cardiac muscle poison and a vasomotor paralyzant. Both of *these forces we wish to preserve, not destroy.* Therefore, after many hundreds of years filled with object demonstrations so plain that they stare us in the face, we are reluctantly beginning to cease teaching our patients well-nigh incurable drug-habits under the guise of beneficial treatment.

THE CRISIS

This interesting and very little understood phenomenon and period are full of danger as well as promise for the patient. Radical changes take place suddenly in both the tissues and in the functions of the body, and the resulting shock to the vital centers is severe. The sudden fall of temperature, the tremendous expenditure of nervous and chemical energy entailed in the final overthrow of the toxemia, the almost instantaneous relaxation of the tired heart, all must be met by artificial warmth, by absolute rest and sometimes even by the use of cardiac stimulants, especially by atropin. The external application of heat (hot blankets, hot-water bottles, etc.), hot water or lemonade given internally, and the cessation of all active treatment for the moment, will enable the patient, as a rule, to pass through this narrow channel into the harbor of final safety.

AFTER-TREATMENT — CONVALESCENCE

The convalescence is by no means an easy road following a severe pneumonia, especially of the bronchocatarrhal type. Every tissue has been poisoned in the toxemia, and the heart and kidneys bear the stress of the storm. Ample time is required for a genuine rebuilding of energy and vitality; and in no other condition is it so true that "haste makes waste" as in the convalescence following a toxemia of the pneumonic type. There is another danger that decreases as the days pass, but is very real during the first active movements of self-locomotion. I have known three formerly strong, vigorous men, in their convalescence from a pneumonia, rise from their chairs to greet relatives and fall over dead from a pulmonary embolus. This possibility calls still more urgently for care in the matter of too early exertion. As many patients are denied a full return to power and health by a too early resumption of the strenuous life as by the exigencies of the acute illness. The daily routine should be resumed step by step only, and organs like the heart and liver and kidneys should for many a day be regarded as objects of care and concern.

DELAYED RESOLUTION

Occasionally the resolution of the consolidated lung comes to a standstill for reasons that are difficult if not impossible of explanation. In such a case, counter-irritation in the form of blisters, dry cupping or iodin applications may be tried. In more than one instance I have seen unresolved consolidation mistaken for a pleural effusion, and resolution follow promptly on the puncture of the lung by the needle. There is little doubt in my mind that this method may be used to advantage for stimulating sluggishly healing lung processes. More important is the general hygienic upbuilding of the patient, which will go far toward recommencing and completing the work begun at the time of the crisis.

CONCLUSION

In glancing back over this outline of the treatment of the pneumonias, it gives some satisfaction to recall the fact that the vast majority of strong, previously healthy persons with the pneumonias ought to recover, as many do, with little or no treatment, except good nursing and scrupulous intestinal care. One might almost say that few, if any, otherwise healthy children should die from either type of the disease. There is no question as to the fact that many pneumonia patients are hurried, if not helped, into the grave by overtreatment.

"Purging, diet and bathing" were the watchwords of Asklepiades, and of a long succession of the ancients. Add both cold and warm clean air to this triad and we shall have before us the outline of the most successful modern treatment of one of the most treacherous and dread forms of systemic and pulmonary disease.

1827 Spruce Street.

Minimum Wage Law and Women.—An industry which does not pay its employees enough to cover their necessary cost of living is a parasite on the homes of the poor and is subsidized by its employees. If any industry is so important to the community as to deserve to be sustained by a subsidy, such a subsidy should come from some other source than its working girls. The principle on which the act is based is that the welfare of women must take precedence over any commercial consideration. The mothers of the future generation should not be sacrificed to industrial gain.—Father O'Hara, Chairman Oregon Industrial Welfare Commission, in *Survey*.

THE DIFFERENTIAL DIAGNOSIS OF CHOLELITHIASIS FROM GASTRIC AND DUODENAL ULCER

WILLIAM J. MALLORY, M.D.
Instructor in Medicine in the George Washington University, Department of Medicine, and Attending Physician to the Outpatient Department of the University Hospital
WASHINGTON, D. C.

The statement so frequently made that gall-stones, in a large percentage of cases, produce no symptoms, is misleading and requires some qualification. It is true that they are often found during operation or post mortem when their presence has not been suspected, but in most cases symptoms were present, and were attributed to disease of some organ other than the gall-bladder, usually the stomach or duodenum and sometimes the appendix.

Recognition of this fact has induced some authors to group cases in two classes: (1) those giving direct symptoms, unmistakably indicating gall-bladder disease; (2) the group presenting indirect symptoms referred to other organs. It is to the group presenting symptoms of uncertain meaning that attention is invited, because it is in this class that difficulty is especially apt to be encountered in establishing a correct diagnosis.

A brief reference to the embryology and physiology of the organs involved may explain the causation of some symptoms, and thus lead to a more accurate interpretation of their meaning. It will be recalled that the liver develops as a pair of hollow outgrowths from the upper part of the duodenum. At a certain stage in this development the right and left hepatic ducts open separately into the duodenum; but later the duodenum becomes pouched where they enter, and this pouch is drawn out to form the common bile-duct, from which the gall-bladder and cystic duct arise as a hollow evagination. These structures are innervated by the same nerve that supplies motor and secretory fibers to the stomach; that is, the vagus. In addition, they are intimately connected with the same sympathetic ganglia, and receive terminal fibers from the same spinal nerves, namely, the four lower dorsal and the two upper lumbar nerves.

In addition to purely reflex disturbances, dependent on the above-mentioned anatomic relations, pathologic changes often involve the stomach, duodenum or colon through the formation of adhesions, which cause traction, dislocation or obstruction, and produce symptoms of organic disease in these organs. It is easy to see that in these relations there exists a mechanism capable of producing almost every variety and degree of disturbance in the motor, secretory and sensory functions of the stomach. It must also be remembered that either functional or organic disease of the stomach may coexist with gall-bladder disease without a causal relation of the one to the other.

The physiologic relation existing between the stomach and gall-bladder is another cause of confusion in the interpretation of symptoms. For example, it is frequently stated that the onset of an attack of biliary colic bears no relation to the ingestion of food. This is true in some cases, because there are other conditions which may induce contractions of the gall-bladder, such as severe exercise; but eating will also do this, for the reason that contractions of the gall-bladder are normally produced by the passage of the duodenal contents—especially fat and peptone—over the papilla of Vater. Evacuation, therefore, occurs during the later stages of gastric digestion. If, at this time, a stone or bit of tenacious mucus engages in the orifice of the cystic duct and occludes it, what would have been a painless evacuation becomes a biliary colic.

The diseases mentioned as most frequently simulating biliary colic are gastric or duodenal ulcer, appendicitis, right-sided kidney lesions, such as nephrolithiasis and Dietl's crises. Rarer conditions, which should not be forgotten, are right-sided pleuritis, the gastric crises of locomotor ataxia, lead colic and aneurysm of the hepatic artery. Kidney lesions may be recognized or excluded by examination of the urine, ureteral catheterization and roentgenographic examination. The correct diagnosis of gastric and duodenal ulcer is especially important from the fact that gastric symptoms commonly occur in biliary disease, while an attack of biliary colic is not always characteristic. Instead of a sudden onset with sharp pain in the right hypochondrium, radiating to the back and shoulder, which may occur at night, and have no relation to eating, it often begins, during digestion, with moderate pain in the epigastrium, which gradually increases in severity until vomiting occurs, sometimes with consequent relief. If in such a case as this the stomach should be examined, hypochlorhydria is often found, or, more frequently, hyperchlorhydria; and in those cases in which the pain has not been severe enough to produce emesis, food remains are found in the stomach eight or more hours after eating.

Such findings are especially apt to attract the whole attention of the examiner to the stomach, and a wrong diagnosis may be made. There are, however, certain characteristics by which primary gastric disease and reflex disturbances may be distinguished. Although biliary colic may and sometimes does occur during the period of gastric digestion and is related to taking food, it will be noticed that the most harmless food sometimes induces an attack of maximum severity, while occasionally the patient can eat the coarsest solid food without discomfort. Between attacks the health remains good. The duration of the pain does not correspond with that of gastric disease. It is often much shorter and sometimes terminates suddenly. In other cases it continues for several hours after the stomach is emptied, either normally or by lavage or emesis.

Local tenderness is of greater diagnostic significance than pain, but even this is of uncertain value, because it is also present in nearly the same region in duodenal ulcer. The tenderness of ulcer is, however, usually more circumscribed than that of gall-bladder disease. Tenderness of the gall-bladder or liver is never absent when a calculus or inflammation is present. It is best elicited by pressing up under the margin of the ribs at the moment of deep inspiration, and is recognized as a diffuse deep-seated pain felt at the moment the edge of the liver touches the hand. The so-called dorsal tender point is present in both gastric ulcer and cystic disease, but with a certain difference. Boas describes increased tenderness to pressure on the right side 3 finger-breadths from the spine, extending from the twelfth thoracic to the first lumbar vertebra. This is present in the interval as well as during the attack and in the absence of tenderness over the gall-bladder. The dorsal tenderness of ulcer is very rarely limited to the right side, but is more common on the left side or both sides, and is more extensive up and down the spinal column.

Jaundice is of little value as a diagnostic sign, because it occurs in less than half the cases of cystic disease and occurs in other conditions simulating biliary colic, notably duodenal ulcer.

Fever, being due to infection, is absent in uncomplicated cholelithiasis. When present, it indicates inflammation of considerable degree and duration, because the lymphatic supply of the gall-bladder is poor and absorption of toxins is slow. In the first few attacks the absence of fever is therefore of little significance, its presence indicating cystic disease rather than gastric or duodenal ulcer.

Examination of the feces will often produce evidence of value in differentiating cystic from gastric disease. Obstruction, if present, may be recognized, and occasionally in cases scarcely suspected a gall-stone may be found, which is of such importance that it is worth the trouble of a careful search. The presence or absence of occult blood must be interpreted with great care after due consideration of the symptoms and duration of the illness. In this connection it is to be remembered that ulcer and cystic disease may coexist. The severe vomiting of biliary colic sometimes produces hematemesis, and the passage of a stone as well as an ulcerating gall-bladder may cause the appearance of a minute amount of blood in the stool and lead to a false diagnosis of gastric ulcer. Briefly, the presence of occult blood does not help in the diagnosis, but its absence excludes active ulcer of the stomach or duodenum.

The following clinical reports serve to illustrate how closely cholelithiasis may simulate gastric and duodenal ulcer:

Case 1.—Miss A., aged 56, for two years prior to examination felt mental depression and sluggishness after meals, and three or four times a year had what was called "acute indigestion." The attacks began a variable length of time after eating, consisted of pain in the epigastrium radiating to the back, nausea and vomiting, and continued an hour or more, usually until some such hard food as bacon, slaw or curds had been ejected. Between the severe attacks she suffered after meals with distention of the stomach, eructations and nausea. The appetite became poor, and the attacks increased in frequency and severity.

When examined the patient was found to be healthy-looking, well nourished and free from fever and jaundice. There was moderate tenderness 1 inch to the right of the median line, 1 inch above the umbilicus and over the tenth rib posteriorly just to the right of the spinal column. An examination of the gastric contents after a test-breakfast showed a total acidity of 54, and a trace of occult blood.

While the patient was on a meat-free diet, the feces were repeatedly examined, and occult blood found on every occasion. During the period of observation she had a very severe attack of pain and vomiting half an hour after eating a cracker and drinking a glass of milk. On another occasion she ate milk toast and suffered a similar attack two hours later. Such attacks occurred repeatedly a variable time after eating soft food. Although blood was present in the gastric contents and stool and vomiting afforded relief, doubt was thrown on the diagnosis of gastric ulcer by the occurrence of sharp attacks of pain and vomiting a variable time after eating the mildest food. During the systematic examination of the feces, three gall-stones were found.

Case 2.—Mr. L., aged 27, was first examined June 14, 1911. He had undergone appendectomy in 1908, and was operated on for exophthalmic goiter about May 7, 1911. The patient, when seen, complained of severe pain in the epigastrium, radiating up under the ribs toward the back, which occurred about every second day, regularly two hours after the principal meal, and continued for two or three hours, unless relieved by hot applications.

Tenderness, 1 inch to the right of the median line, and 1 inch above the level of the umbilicus, was noted. A slight subacidity was found after a test-breakfast. The total acidity was 38. The bowels were constipated and the hard scybalous feces contained occult blood on every examination.

Under the treatment for duodenal ulcer, the attacks of pain decreased in frequency and severity and the patient gained weight. July 13, 1911, the patient had a mild attack of abdominal pain before breakfast. September 11, 1911, a severe attack of abdominal pain occurred, with tenderness over the region of the appendix and ascending colon. The temperature was 99 F. September 14, after consultation with the surgeon who originally referred the case for examination, the patient was taken to the hospital. Attacks of abdominal pain, muscular rigidity and slight elevation of temperature (99 to 100 F.), with moderate leukocytosis (9,000), recurred at intervals of a few days, but finally subsided and the patient left the hospital free from symptoms. Six months later, March 10, 1912, there was another severe attack of abdominal pain, without fever. April 9, 1912, an attack began at 6 a. m. and was followed by headache, chilliness, a pulse rate of 100 and a temperature of from 100 to 102. The leukocytes numbered 7,600. A slight jaundice developed for the first time April 14, 1912. On rest and cold applications the acute attack subsided.

April 18, 1912, at operation, the gall bladder, duodenum, pylorus and a part of the transverse colon were found embedded in a mass of dense adhesions. The gall bladder contained a number of stones, was ulcerated and very closely adherent to the transverse colon. Apparently it had once perforated into the colon and the opening subsequently became closed by the contraction of the adhesions. The patient has remained well until the present time, more than two years after operation.

In this case, the pain at regular intervals after eating, blood in the feces and tenderness in the right hypochondrium led to a wrong diagnosis of duodenal ulcer. This diagnosis was, of course, revised when it was observed that the pain occurred at irregular intervals and without relation to eating. One naturally asks, Were the gall-stones present three years previously when the appendix was removed?

CASE 3.—Mrs. R., aged 40, was first seen Jan. 24, 1913. Her mother died of cancer. About eleven years prior to examination she had a pelvic operation performed. The uterus was "suspended and a tumor and glands removed."

For seven or eight years she had occasional attacks of "acute indigestion." At first the attacks were rare, intervals of months or even years intervening during which she could eat anything without discomfort or pain. The attacks became much more frequent, especially in the month preceding examination, during which time she had three or four attacks. These occurred always four or more hours after eating, but never during the day. The pain was described as vise like in character, was located in the epigastrium, increased in severity until she was doubled up and was accompanied by a cold sweat. Food, whisky and even large doses of morphin sulphate failed to relieve the pain entirely, but it usually disappeared gradually by morning. Vomiting often occurred or was voluntarily induced with partial relief.

The patient was stout, well nourished and of good color. There was slight tenderness over the pyloric region. After a test breakfast, about 100 c.c. of nearly clear fluid was aspirated, which was free from any trace of occult blood, and contained no hydrochloric acid, either free or combined. The feces were also free from occult blood. After a test supper of raisins and rice there was epigastric pain which increased in severity, and continued until the physician was called eight hours later. The stomach was then irrigated and a large quantity of the supper removed. The pain continued until relieved by morphin. Gall-stones were suspected, but in order to exclude pyloric stenoses a roentgenogram was made, which showed a gall-stone impacted in the cystic duct. The stomach appeared to be free from deformity.

At operation the gall-stone was removed, and no lesion was found in the stomach, pylorus or duodenum.

CYSTS OF THE PROSTATIC URETHRA

A. J. UNDERHILL, M.D.
BALTIMORE

Because of the apparent rarity of the condition, the following cases are of interest:

CASE 1.—W. M. R., aged 36, unmarried, complained March 20, 1913, of "impotence." His family history was unimportant. He had had typhoid thirteen years before. The patient gave no history of syphilis, but he had had a number of attacks of gonorrhea, one of which was complicated by epididymitis of the left testicle. Seven years before he had been massaged for some weeks for prostatitis, since then he had had no urethral disturbance except dribbling after micturition and gluing of the lips of the meatus. His habits, sexual and otherwise, were good.

A few hours before consulting me he had attempted intercourse and failed utterly to induce an erection. He stated that he was in excellent health, but for some months past had been easily exhausted and had felt tired from his waist down. He had not attended to his work with his customary feeling of energy. He had not attempted coitus during the preceding two years, although before that time he had led an unusually active sexual life.

Examination showed the external genitalia to be well developed and normal. There was no urethral discharge and the urine (three glass test) was negative with the exception of a few shreds in the first glass. The whole surface of the prostatic urethra from the margin of the internal vesical sphincter to the beginning of the membranous urethra was found, on endoscopy, covered with cysts from 1 to 2 mm. in diameter, round or somewhat oval, with the long axis corresponding generally to that of the urethra. Two of them just external to the vesical orifice were larger, measured about 4 mm. in their long diameter, and lay transverse in the wall of the urethra. No normal mucous membrane was visible, even the colliculus being included in the cystic degeneration.

CASE 2.—An unmarried clerk, aged 26, complained May 21, 1913, of a gleet for which he had been under treatment by prostatic massage for eight months. He had had an attack of gonorrhea five years ago but gave no history of syphilis or other venereal diseases. When an examination was made a transparent mucoid discharge which microscopically consisted of mucous shreds, epithelium and a few pus cells but no gonococci, was expressed from the meatus. The urine (three glasses) was negative with the exception in the first glass of a few fine shreds made up of epithelium and pus cells.

The endoscopic examination showed practically the same condition in the prostatic urethra as in Case 1, except that the site of the lesion began within the margin of the internal vesical sphincter, which was smooth and normal in appearance and extended 1.5 cm. anterior to this point. The whole circumference of the urethra within this area was the seat of the change. The mucous membrane of the prostatic urethra was hyperemic, bled easily and in places was granular in appearance. The colliculus was apparently normal.

Both the cysts were sessile, white and looked in general like pearls sunk half way in the mucous membrane. They were insensitive to the touch of the probe or swab and did not bleed except when incised, the walls varied in thickness, those of the smaller cysts consisting of a thin membrane which collapsed completely when incised or torn, while the larger cysts were quite resistant to the endoscopic knife and did not collapse entirely when opened. The contents, which were withdrawn with a syringe after incision, appeared to consist of a clear fluid which, microscopically, contained no cellular elements or organisms. This examination, however, was unsatisfactory on account of the presence of red blood corpuscles as a result of the incision, which did not in itself cause enough bleeding to interfere materially with further procedures. No cultures could be taken at the time.

In the first case the condition of the margin of the sphincter was well shown. When the endoscope was pushed into the bladder and slowly withdrawn, in place of the smooth, rounded, bright red circumference of the sphincter internus which normally comes into view and closes on the extremity of the endoscopic tube like an iris diaphragm, a series of grayish-white excrescences was seen, irregular in size, each semicircular at first view, but losing this shape as they came together and were compressed by the contraction of the sphincter. As the tube was withdrawn through the prostatic urethra the cysts continued to come into the field of vision in one thick continuous cluster which was crowded together in a formless white mass as they disappeared in the apex of the funnel formed by the collapse of the walls of the urethra behind the end of the tube.

A cystoscopic examination showed a normal bladder in each case. The extension of the process to the margin of the internal sphincter in Case 1 was demonstrated by the corrugated line which the border of the orifice assumed across the lens of the cystoscope, each corrugation corresponding to a cyst, which indicated that the cysts extended around the circumference of the sphincter without invading the bladder. That this caused an imperfect closure of the internal sphincter in this instance was evidenced by the difficulty of keeping the field dry while the cysts were being treated through the endoscope. The end of the tube would be flooded with urine with a regularity suggesting the functioning of the ureters.

The treatment consisted of extreme dilatation with the Kollmann posterior dilator, and incision of the cyst walls. A few dilatations served to destroy the small thin-walled cysts except a few within the margin of the internal sphincter. These and the larger cysts with thick walls were treated by incision followed by cauterization with the solid silver nitrate stick. An immediate improvement followed. The first patient recovered completely. The second still has a mucoid discharge. The few neurasthenic symptoms he showed have improved.

Although but few of these cases have been reported in the literature, I believe that were the endoscope used more often conditions such as I have described would be found more frequently. Solitary cysts of the prostatic urethra are not uncommon. Many of them are found in the fossae between the colliculus and the lateral walls of the urethra and are probably retention cysts of the prostatic ducts. In one case a cyst covered the orifice of the left ejaculatory duct. The patient, a physician, was a marked neurasthenic. The left lateral prostatic lobe was larger than the right, although not tender on pressure. The left seminal vesicle was distinctly more distended than the right. The mere touching of the verumontanum with a swab caused a flow of secretion containing spermatazoa into the endoscopic tube showing the marked irritability of the part. There was no history of venereal infection.

The solitary cysts in this region differed in appearance from the cysts of the multiple variety which I have described. They were bluish-red, larger (from 5 mm. to 8 mm. in diameter), had the general appearance of blebs, and when incised, collapsed completely, leaving a distinct depression in the mucous membrane.

The origin of these cysts is as yet not altogether clear. J. Englisch,[1] in seventy necropsies on new-born infants, found, in five cases, cyst-like bodies at the border of the sinus pocularis, which he concluded were retention cysts formed as the result of a malformation or congenital inclusion of glands in this region. They caused obstruction to the passage of urine but usually ruptured either which had invariably accompanied ejaculation since puberty. A section of the wall of the cyst showed the mucosa of the sinus pocularis, the prostatic urethra, and the intervening layers including some of the glands of the mucosa. Its treatment by incision and cauterization resulted in a cure of the local and neurasthenic symptoms. Buerger and Oppenheimer[4] found a cyst of the prostatic urethra just within the margin of the internal sphincter at necropsy in a man who had died of peritonitis. The cyst was 6 mm. in diameter, had a number of very small cysts in its immediate vicinity and contained a mucoid greenish-yellow fluid with a few desquamated epithelial cells. They considered at that time that the location of the cyst was unique. Subsequent observations have shown that the condition may be more frequent than they supposed, for in a later article Buerger[5] described a number of such cases; among them he had observed three, which, like the two I have described, showed a cystic degeneration involving large areas of the prostatic urethra. All of these patients gave a history of one or more preceding attacks of gonorrhea, which were more or less protracted. This seems the only etiologic factor they have in common.

The pathology of this condition is more or less obscure. It is possible that they are retention cysts formed by the occlusion of the ducts of glands in the mucosa brought about by inflammatory changes. The mucous membrane of the prostatic urethra in the adult is apparently but scantily supplied with glands. Paschkis,[6] however, states that he has observed in the epithelium of the mucosa of the prostatic urethra, especially in the young, involution groups of cells, which differ in size, nuclei, staining properties and general characteristics from the surrounding cells; these, while possessing no mucus contents, no doubt represent, in his opinion, intra-epithelial glands, which are either in a state of functional rest or in process of development. Stoerk[7] and Zuckerkandl[8] found small collections of mucus in normal and pathologic cases, which, by pressure on the surrounding cells, formed cystic cavities. Stoerk held them as the after-effects of a pathologic process; Zuckerkandl considered these small collections as physiologic, but when numerous and large, as pathologic. If such is the case, the history of preceding attacks of urethritis given by these patients is significant.

The local symptoms were not distinctive; they were the same as we see in any long-standing chronic urethritis. The subjective symptoms, if any were present, were those characteristic of the neurasthenia accompanying many of the chronic diseases of the posterior urethra. They were the predominating feature in the first patient. This is often the result when the verumontanum is involved in a pathologic process.

CONCLUSIONS

1. A cystic degeneration of the posterior urethra may follow a preceding inflammation of the part.
2. There are no symptoms characteristic of this particular affection.
3. The only method of diagnosis is by endoscopic

EQUIPMENT OF A SMALL HOSPITAL: MAKING OVER A DWELLING-HOUSE *

JOHN ALLAN HORNSBY, M D.
Hospital Consultant to the Board of Commissioners of Cook County
CHICAGO

The time is rapidly approaching when every community of any size or importance must have adequate hospital facilities to take care of all the sick in the community; but this is not the case to-day. There are many communities of importance and considerable population whose hospitals, when they have any at all, are wholly inadequate to take care of the needs of the community in accordance with the modern demands of medical science. This means that in such communities the medical profession is far in advance of the hospitals. The grave responsibilities of the physician will not permit him to allow a condition of this sort to prevail if he can help himself, and thousands of most excellent physicians and surgeons in this country to-day are casting about for some scheme by which they can give to their patients modern surgical and medical attention. A great number are meeting this problem by acquiring and remodeling dwelling-houses in their neighborhoods and equipping these the best they can to do the work which they feel they cannot get done elsewhere. So important has this problem become within the last two or three years and so many inquiries are coming to hospital administrators everywhere from physicians that it was thought a brief paper on this subject might not be out of place.

Figure 1 shows a single house somewhat isolated from surrounding structures, thus giving plenty of fresh air and sunshine. This house occupies a position on one of the downtown streets of a town of about 15,000 people. Its owner, rather a well-to-do business man, was forced to move away by the encroachments of business. This house was rented for years and fell into a state of shabbiness and poor repair. The upper half story will lend itself nicely in the remodeling process to comfortable quarters for some of the help. Figure 2 shows the entrance, the small hallway, a staircase leading to the second floor, a closet under the stair and an opening from the hall into the dining-room. In this particular house there was a second or back parlor instead of the single parlor as shown in the illustration. A side porch to the rear gave abundant air-space downstairs. This parlor could be used for a parlor, a reception-room for a small hospital, or for two or three beds

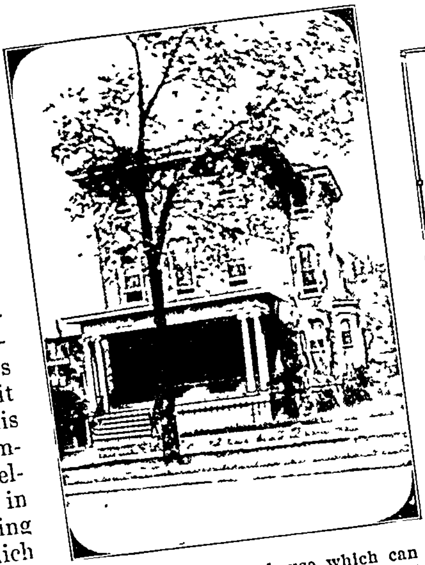

Fig 1.—A single house which can be remodeled, the upper half story lending itself to comfortable quarters for help.

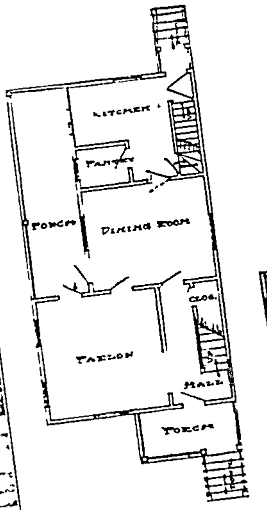

Fig 2.—The ground-floor plan of the house shown in Figure 1 A side porch to the rear gives abundant air-space

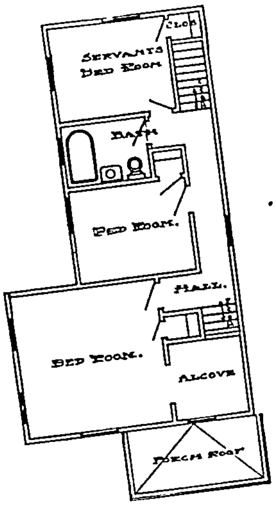

Fig 3.—The second-floor plan of the same house. A bedroom toward the rear will make an operating-room by knocking out the north wall and putting in glass

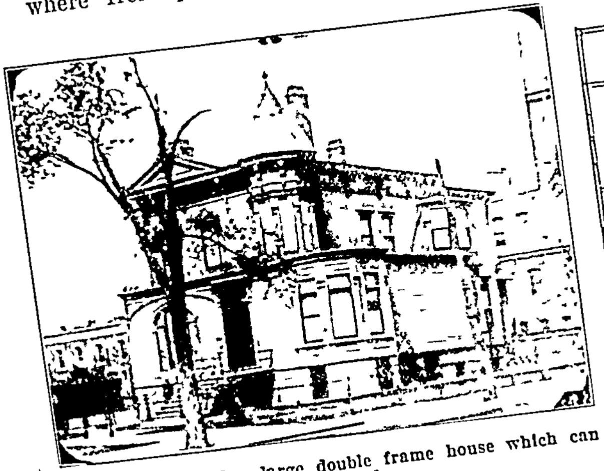

Fig. 4.—A rather large double frame house which can be used if nothing better is found.

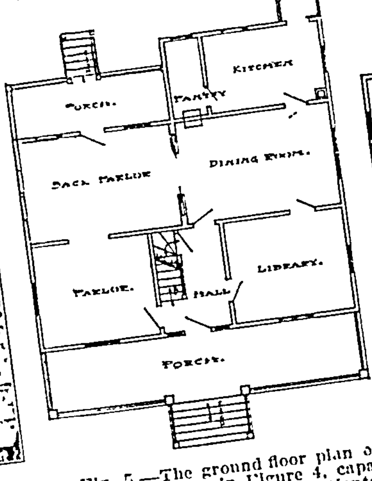

Fig 5.—The ground floor plan of the house shown in Figure 4, capable of taking care of four patients. It need not be remodeled, but some repairs are necessary.

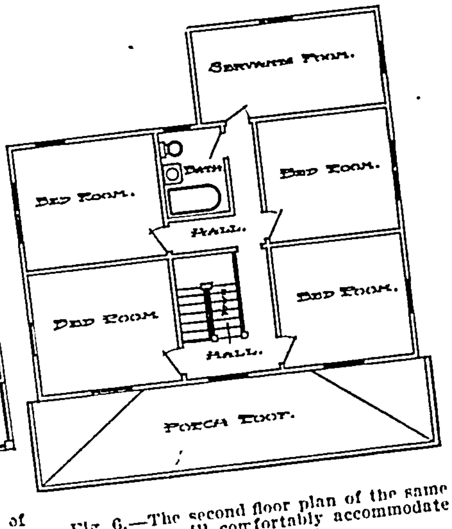

Fig. 6.—The second floor plan of the same house, which will comfortably accommodate from ten to fourteen patients.

---

* Read in the Section on Hospitals of the American Medical Association, at the Sixty-Fourth Annual Session held at Minneapolis, June, 1913.

* Because of lack of space this article is abbreviated in The Journal. The complete article appears in the author's reprints.

as the proprietor found necessary. The dining-room would be used for a dining-room for well people as well as for convalescents. The kitchen and pantry will lend themselves very nicely for the small, private hospital purposes. Figure 3 shows the second floor with large bedroom and alcove, which may be used together for three or even four patients. Along the hall, toward the rear, is a second bedroom with one window and closet.

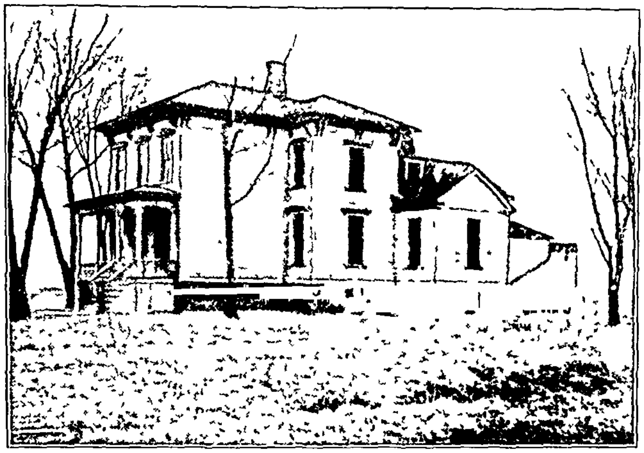

Fig. 8 —Farmhouse, later used for the Chicago Fresh Air Hospital, before alteration

Farther to the rear are the bath and water-closet and still farther another bedroom with windows on two sides. This was formerly a servants' room but will be large enough for one, and under necessity, two patients; or better still, a very nice surgical operating-room can be made of this room by knocking out the north wall and putting in glass.

Figure 4 shows a rather pretentious double frame house by no means ideal for a hospital, but capable of being made to do very nicely if nothing better can be found. Figures 5 and 6 show the first and second floor arrangement. Practically no modifications need be made in this house except whatever repairs are made necessary by its neglected condition. It will comfortably take care of four patients down-stairs and from six to ten patients up-stairs.

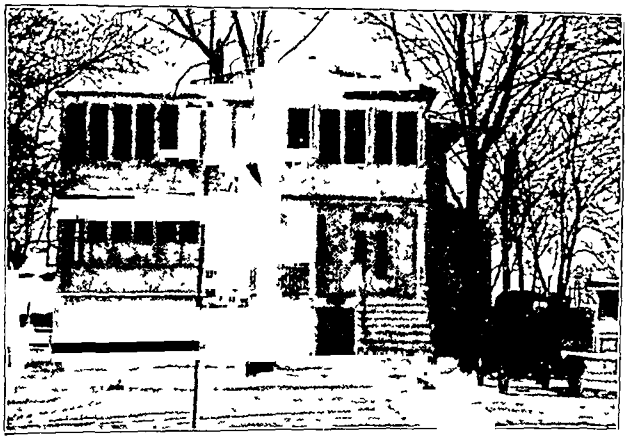

Fig. 9.—Front view, after alterations

Figures 8 to 16 give a meager suggestion of a plan that worked out extremely well. They give views and floor-plans of the Chicago Fresh Air Hospital, which Mr. James A. Patten of Evanston created, and the work of alteration on which was done by Mr. Meyer J. Sturm.

This was an old rambling farmhouse. Figure 8 shows the house before the remodeling, Figure 9 shows a front view after the porches have been enclosed. Figure 10

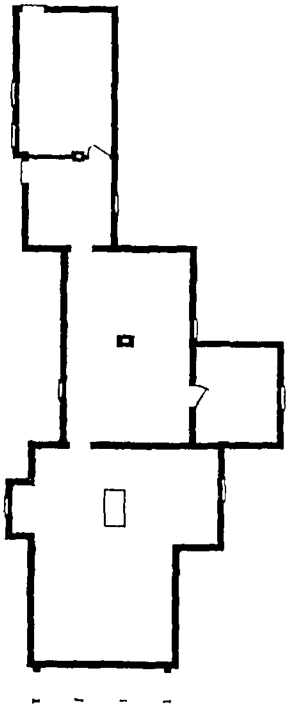

Fig 10 —The basement of the Chicago Fresh Air Hospital, before remodeling

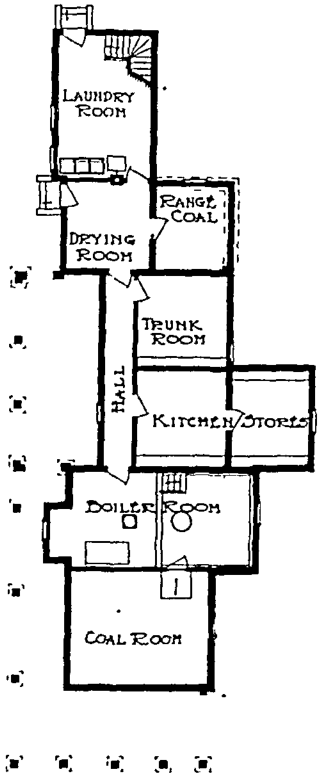

Fig 11 —The basement in its remodeled state.

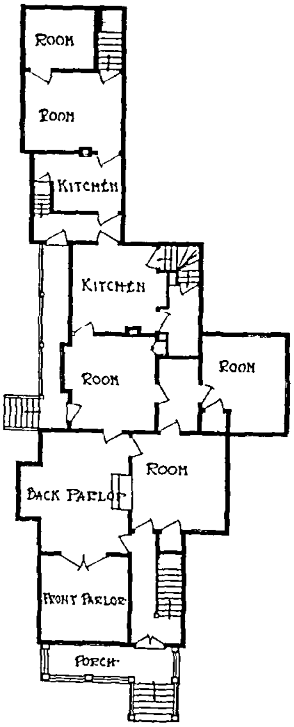

Fig 12 —The first floor plan before remodeling.

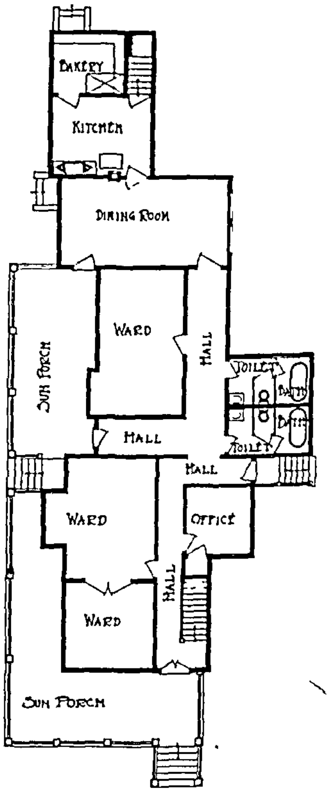

Fig. 13 —The changes made in the first floor.

shows the basement before remodeling, and Figure 11 shows the changes that were made in the basement. Figure 12 shows the first floor before the changes were made and Figure 13 shows the first floor afterward. The complete remodeling of this house cost less than $1,500, and it was made acceptable for the accommodation of forty-one patients. Figures 14 and 15 show the second floor before and after alterations. Figures 17, 18, 19 and 20 show a most interesting transformation of a residence into a 108-bed children's hospital. Two brothers, Messrs. Lyman, gave to the city of Minneapolis their two residences, occupying a block of 400 by 500 feet, one of the houses facing on one street and the other facing the next parallel street, so that the two houses backed up to each other with an intervening space of 100 feet. The smaller of the two residences was altered into a service building and home for nurses; the other was modified as shown in the figures. The cost of all alterations and equipment for both houses was approximately $5,000.

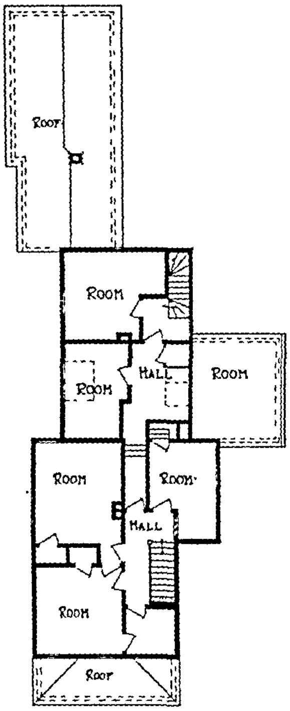

Fig. 14.—The original second-floor plan.

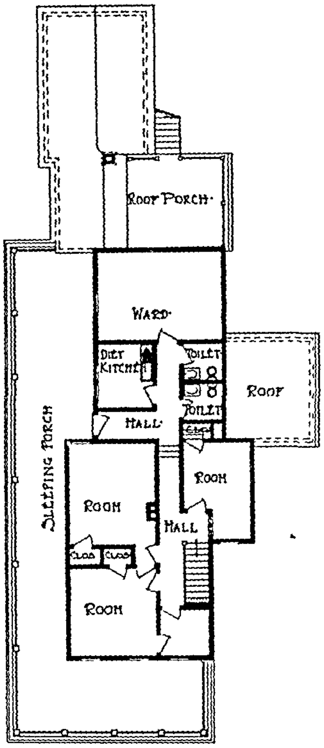

Fig. 15.—The second floor after remodeling.

THE EQUIPMENT OF THE SMALL HOSPITAL

In contemplating the equipment of one of these small dwelling-houses for hospital purposes, about the only thing that need be thought absolutely necessary is a small sterilizing-plant made up of water, dressing, utensil and instrument sterilizers. This plant adequate in size should be as follows:

2 six-gallon water sterilizers.
1 dressing sterilizer 16 by 24.
1 utensil sterilizer 16 by 16 by 18 inches.
1 instrument sterilizer 6 by 9 by 12.
Cost of sterilizing plant, $300.

The balance of the equipment for a hospital of this sort follows, with approximate prices which will have to be paid for the several articles, the whole equipment to cost approximately $952.50 plus $40 for each patient more than one, since the bed equipment for only one patient is counted.

THE OPERATING-ROOM EQUIPMENT

One of the principal reasons why the physician must have a hospital at all is to do surgery there, whether it be general surgery or the surgery of a specialty, as in eye, ear, nose and throat work, genito-urinary surgery, gynecology or orthopedics. A very simple equipment for such a room will be as follows:

1 table	$25.00
1 small cabinet	50.00
Ether masks, @ $1, or gas masks and apparatus, or both	75.00
Basin and arm plunge on stand	10.00
1 low stool for anesthetist, etc.	4.00
1 small table for anesthetist	4.00
1 instrument table, with extension	6.00
1 small table for surgical nurse	4.00
Cost of operating-room equipment	$178.00

WARD AND NURSING EQUIPMENT

In such a hospital we shall have one or two rooms for two or three patients each and perhaps two or three rooms for private-room patients, and I am considering now a hospital to contain, say, from ten to fifteen beds, and at this particular place the things necessary to nurse patients which will be used in common in all parts of the house and for all patients. These are:

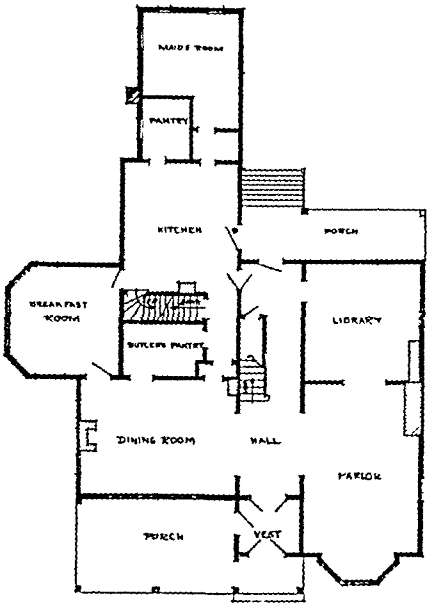

Fig. 17.—Lymanhurst, first-floor plan, before alterations.

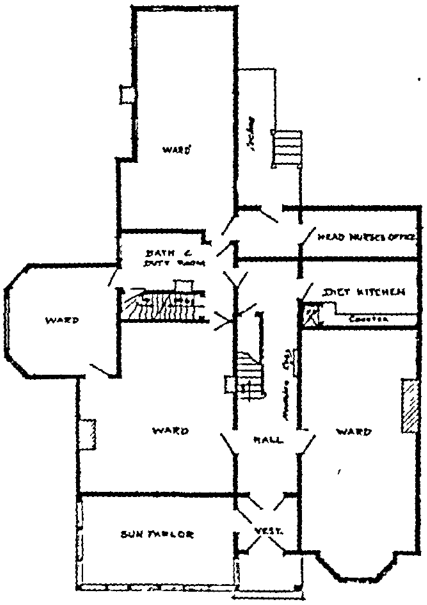

Fig. 18.—Lymanhurst, first-floor plan, after alterations.

Water or air mattress (latter preferred)	$25.00
1 dozen hot-water bottles (rubber)	15.00
1 dozen ice-bags (rubber)	12.00
1 dozen male urinals	12.00
Carried forward	64.00

Brought forward	$64.00
1 dozen female urinals	12.00
1 dozen nutritive funnels	3.00
1 dozen nutritive cans	12.00
2 stomach tubes—2 sizes	2.00
½ dozen soft rubber catheters	3.00
100 feet gum tubing, assorted sizes	8.00
½ dozen Perfection bed-pans	15.00
½ dozen Eureka bed-pans	9.00
3 packages assorted size orangewood splint mat	3.00
1 package strawberry-box wood	2.00
100 pounds hospital cotton	15.00
50 pounds oakum	3.00
100 pounds cotton batting	10.00
200 pounds rolled bandages, assorted widths and sizes, @ $0.35	70.00
1 Commode, chair and vessel	10.00
Cost of ward and nursing equipment	$241.00

EQUIPMENT FOR THE PATIENT—PER BED AND PER PATIENT

1 bed	$8.00
1 mattress	8.00
2 pillows	4.00
2 blankets	6.00
1 dozen sheets	6.00
1 rubber sheet	3.00
1 dozen towels	2.00
½ dozen bath towels	1.50
1 hair pillow	1.50
Cost of equipment per bed	$40.00

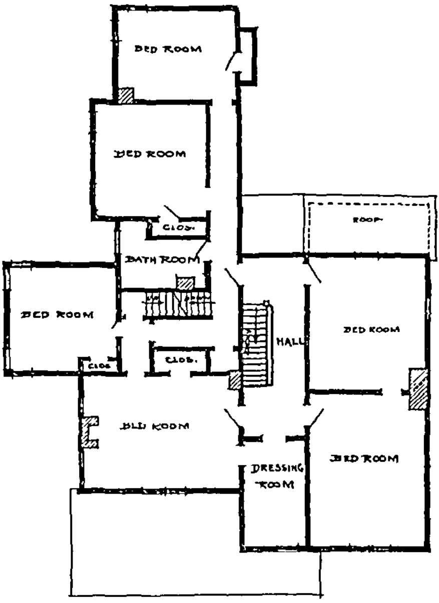

Fig. 19.—Lymanhurst, second-floor plan, before alterations.

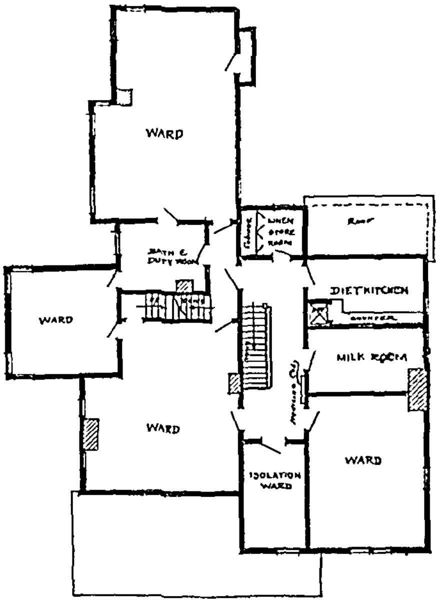

Fig. 20.—Lymanhurst, second-floor plan, after alterations.

Now we have equipped our little hospital except for the kitchen and dining-room service, and this will differ in no particular from what the same service would be for a private family. An ordinary range will cost from $30 to $50, gas or coal as may be desired; the ordinary kitchen and dining-room utensils will be about as follows:

Range			$50.00
Pots, pans, kettles, knives, forks, spoons			25.00
Cutlery:			
Knives, 3 dozen	@$2.50	$ 7.50	
Forks, 3 dozen	@ 2.00	6.00	
Spoons, large, 3 dozen	@ 2.00	6.00	
Spoons, small, 6 dozen	@ 1.50	9.00	
Dishes:			
Dinner plates, 4 dozen	@ 3.00	12.00	
Breakfast plates, 4 dozen	@ 2.50	10.00	
Bread and butter plates, 4 dozen	@ 1.50	6.00	
Soup plates, 4 dozen	@ 3.00	12.00	
Teacups, 4 dozen	@ 2.50	10.00	
Saucers, 4 dozen	@ 2.00	8.00	
Cereal bowls, 2 dozen	@ 3.00	6.00	
Cake covers, 2 dozen	@ 2.50	5.00	
Vegetable dishes (individual), 6 dozen	@ 1.50	9.00	
Vegetable dishes (large), 1 dozen	@ 6.00	6.00	
Soup tureens, 2	@ 3.00	6.00	
			$118.50
Cost of kitchen and dining-room service			$193.50

We have now spent $952.50 and our little hospital is complete. We must now add $40 for the equipment for each additional patient, since we have given the equipment for only one.

THE WARD UNIT OF THE GENERAL HOSPITAL *

EDWARD F. STEVENS
Hospital Architect, Associate Member American Institute of Architects
BOSTON

A noted architect said to me when I was a young student, "One needs one hundred years to study and then one hundred years to practice what he has acquired." If this is true in general architectural problems, it is doubly true in hospital planning; so that in the brief time allotted me this afternoon I can but touch the high points of the subject given me, "The Ward Unit of the General Hospital."

The ward unit is really the keynote of the hospital, for here the patient (for whom the institution is built) lives, eats, sleeps and spends his weary hours of convalescence. We should therefore never cease to study how to fill those hours with as much comfort as possible, to serve the patient good, palatable food, to guard him from undue noise and excitement from the working of the hospital, and to see that he has fresh air and sunshine. The planning of the ward unit, whether in a hundred-bed hospital or in a thousand-bed hospital, offers the same problem — the best care of the patient.

EUROPEAN HOSPITALS

Within the past few weeks I have visited and made a careful study of half a dozen of the more recent of the European hospitals. As the plans of some of these have never, I think, been shown in this country, it may be of interest quickly to review these general plans before taking in hand the subject of the ward unit. I shall consider these hospitals in the order in which I visited them—the Barmbeck-Hamburg at Hamburg, the Rigs at Copenhagen, the Bispebjerg at Copenhagen and the Munich-Schwabing at Munich.

The Barmbeck Hospital.—The new Barmbeck III City Hospital at Hamburg, now in process of construction by Architect Ruppel, consists of forty-four buildings and will house fifteen hundred patients. The cost will be 9,800,000 marks for buildings and 3,000,000 marks for equipment, total 12,800,000 marks, making 8,533 marks, or about $2,200, per patient. To build the same hospital in this country would cost from $3,500 to $4,000 per patient.

Ruppel's plan for this hospital has differed somewhat from his usual plan; for instance, he has placed the medical-unit center or the bath-house on the axis of his plan; while in the St. Georg, the Eppendorf, the Virchow and other large German hospitals, the bath-house is placed on the medical side, balancing the operating-building on the surgical.

---

* Read in the Section on Hospitals of the American Medical Association, at the Sixty-Fourth Annual Session held at Minneapolis, June, 1913.

Rigs Hospital.—At the suggestion of one of your members, I visited the new hospitals at Copenhagen—the new Rigs Hospital, which has been occupied but a short time, and the Bispebjerg, which will be completed this year.

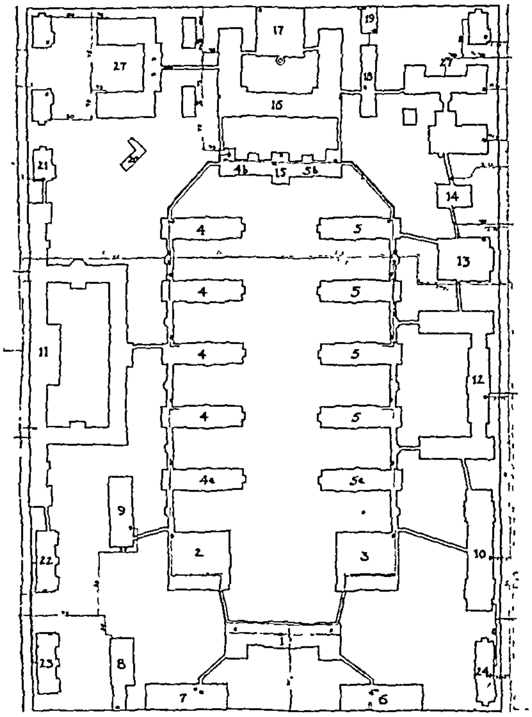

Fig. 1.—General plan of Rigs Hospital, Copenhagen.

The general plan of the Rigs (Fig. 1) is symmetrical, of the pavilion type, with connecting corridors in the main, divided into the surgical on the left and the medical on the right. There is no connection, however, between the medical corridor and the bath-house (13 on plan), which is unfortunate. There is, however, an underground connection to the morgue (14 on plan), and, as our guide expressed to us, she wished for the patient's sake that this arrangement might have been reversed.

The maternity department is one of the largest; here the vast army of unfortunate women which abounds in every large European city is cared for.

The ward unit (Fig. 2) of this hospital is worthy of study, for it is in many ways unique and has much to commend it. The staircase, elevator and noisy parts are kept at the extreme ends, away from the portion occupied by the patients. The serving kitchen, bath-rooms and sink-rooms are on a cross-corridor and the surgical dressing-room (14) and water-closets are removed to the opposite end of the building. The ward itself, containing twenty-six beds, is divided into eight sections, each section containing three or four beds. The dividing screen affords privacy to the patients and still allows free access to all parts of the room for the attendants. An isolation room and nurses' room are placed in the center; bowls for the surgeons' use and medicine-closets are placed in each ward.

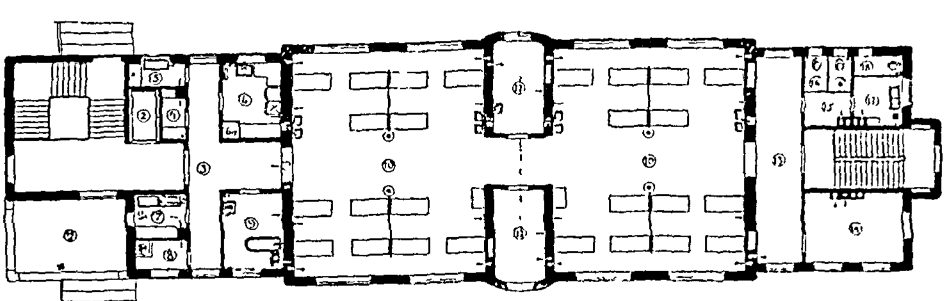

Fig. 2.—Plan of ward unit, Rigs Hospital, Copenhagen.

These screens (Fig. 3), only 6 feet high and 1 foot from the floor, afford the same ventilation as an open ward.

I consider this one of the best-developed ward units that I have seen in Europe.

Bispebjerg Hospital.—The new Bispebjerg Hospital is located on slightly rising ground; the site, containing 51 acres, is surely most ideal. This institution consists of forty-six buildings, two and three stories high. These buildings, while isolated above ground, are all connected by wide, well-lighted underground corridors; but only the six surgical units are connected by above-ground corridors.

I was unable to obtain detailed plans of a ward unit. The service is in the center, with a large day-room on the axis, two sixteen-bed wards at either end, with two six-bed and two three-bed wards. The details of the serving-kitchen, the sink-rooms, the laboratories and the dressing-rooms are most complete.

Every building has its own airing-balconies, and the grounds are laid out with special care for the comfort of patients, with arbors, benches and fountains.

The operating-units, two in number, were not completed, but gave promise of especially good detail. For one thing, the observers of the operation enter from a special door to the space between the outer and inner sashes of the operating-room, which is about 3 feet in width.

Munich-Schwabing.—One of the most modern and complete hospitals in Germany is that at Munich-Schwabing (Fig. 4). Here Architect Schachner has embodied the best of German planning and coupled with it the best of American planning. While he has separate pavilions, he also has everywhere connecting corridors, except to the buildings for contagious diseases and special treatment; and even here there are underground corridors.

The administration department is in the center, flanked by the chapel and nurses' residence on one side and by the offices and home for interns on the other. The surgical group has for its center the operating-building, and the medical unit the splendid bath-house. I should like to describe this bath-house, which I should say is the finest in all Europe to be found in a general hospital, but this is not the subject offered me.

There are no large wards in this hospital, the largest containing twelve beds, and all wards face the south, with opportunities (Fig. 5) for wheeling patients to the gardens and balconies.

The service-rooms are to the north, the day-room central with unit to the south and the laboratory and dressing-rooms on the north. The admitting-department for each ward unit is very complete. The patient is admitted at No. 11 and the clothes are removed and put into a container made of linen, which then hangs on a truck. The patient next goes to No. 12, where he is bathed, to No. 13, where he is given the hospital clothes, and then passes out through No. 8, where final examination is made and history completed, and thence to his room. The elevator at this part of the building is for the convenience of the second-story patients. There are airing-balconies for each flat, which are spacious and comfortable. with attractive window-boxes of flowers decorating the railing in summer.

AMERICAN HOSPITALS

The German hospitals which I have mentioned are supported largely by the government, while in our country conditions are vastly different. Many of our hospitals are owned by private corporations, and it is generally a question of accommodating the largest number of patients for the smallest amount of money. Our architects are forced, therefore, to economize in every way until the ward, in many cases, has become almost a barracks for the housing of patients, the attendants being obliged to put up often with the merest necessities. I am glad to say that some of the newer hospitals are rising in scale and, instead of making a number of rooms and leaving it to the administrator later to put what equipment he can into these rooms, they are allowing their architects to provide some of the more essential units, such as the laboratory, the surgical dressing-room, the sink-room and a serving-kitchen of sufficient size for the work needed, and to design and plan for the equipment at the time of making the drawings

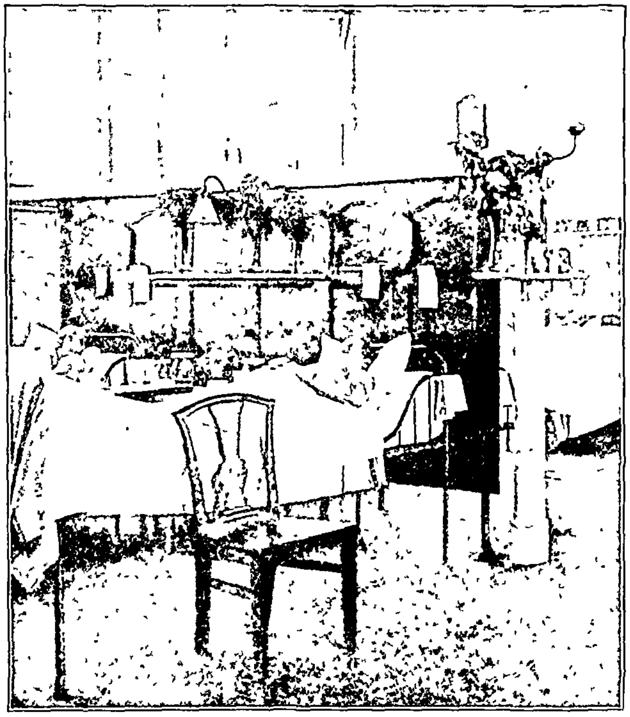

Fig. 3.—View of general ward, showing fixed screen partitions, Rigs Hospital, Copenhagen.

I have described a few of the recent ward units of Europe and would call your attention to some of our newer examples in American hospitals. I shall begin with the ward unit of the hospital of which the chairman of this Section is superintendent.

Peter Bent Brigham Hospital.—The care and thought expended on the working out of the plan of the Peter Bent Brigham Hospital makes it worthy of much study. Here Dr. Howard, with the assistance of his architects and engineers, has developed a ward unit which gives the patient every advantage of the open air, the sunlight and quick and quiet service.

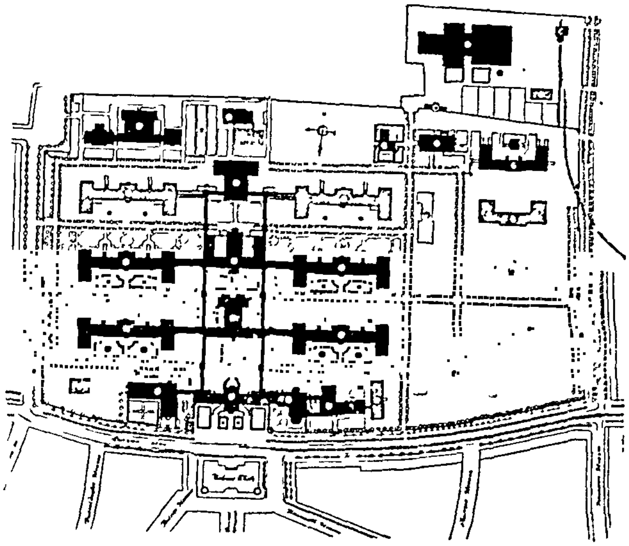

Fig. 4.—General plan of the Munich-Schwabing Hospital.

The staircase and elevator lead directly from the main corridor at the extreme north end of the building.

The first floor of this ward unit contains two large wards, one of eight beds and the other of fourteen beds, and two isolation rooms, while the diet-kitchen, duty-room, baths and water-closets are grouped together on the side opposite the main ward. A cross-corridor is also provided between the two large wards. On this floor there is a laboratory and consultation-room.

On the second story there is one large ward of twelve beds, with two isolation rooms, duty-room and water-closet and ample airing-balconies or terraces, thus providing outdoor space for all patients of this ward unit.

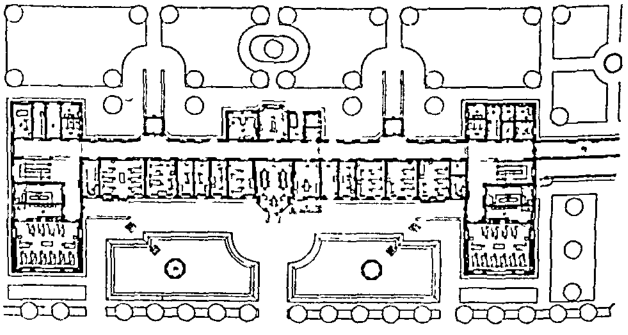

Fig. 5.—Plan of ward unit, Munich-Schwabing Hospital.

Cincinnati General Hospital.—Another carefully planned ward unit which shows the study of European examples is that of the Cincinnati General Hospital (Fig. 6). In this Dr. Holmes has given much thought to the perfection of the ward unit.

The nurses' station, while not directly in the main ward, is in such a position that it commands a view of all of the ward beds as well as the doors of the private rooms.

The patients' water-closet is entered through a fresh-air cut-off on the principle of best-planned English hospitals, while the sink-room is entered through the nurses' work-room or directly from the corridor. Additional water-closets are connected directly with the solarium, thus minimizing the work of the nurses and attendants.

The utilities, baths and toilets are grouped together, while the entrance to the serving-kitchen is directly from the main stair and elevator corridor. A large and commodious dining-room is provided for the patients who are able to be about.

Harper Hospital.—In the six-story building now being erected for the Harper Hospital at Detroit (Fig. 7) an innovation is introduced in the construction by making two 8-foot set-backs in the walls of the main pavilion, so that the first three stories provide for private rooms on either side of a wide corridor. The upper three stories provide for a ward of proper width for administration. This allows on the fourth floor of two large airing-balconies over the roof of the private rooms of the third story.

In this plan, also, the utilities are grouped in the center, with fresh-air cut-off between the main 22-bed wards and the utilities. Water-closets are provided at the ends of the large wards, as well as general water-closets off the main corridor.

On every story surgical dressing-rooms are provided, and on stories containing private rooms a special room for cut flowers is introduced. In this building a large roof ward is provided on the seventh story, with diet-kitchen and other utilities.

Bridgeport Hospital.—In the Bridgeport Maternity and Children's Hospital (Fig. 8) the ward unit is somewhat different from that of any of the other hospitals mentioned in this paper. In the main sixteen-bed woman's ward the principle adopted in the Rigs Hospital at Copenhagen is introduced; that is, there are four groups of four beds each, and these groups are divided by a stationary screen 6 feet or more in height, giving the semi-isolation needed in these rooms.

The crèche, as well as the serving-kitchen and sink-room, is at a distance from the ward and private-room patients.

In this plan an admitting-unit is provided, in which the careful examination and bathing of patients are conducted. Adjoining this admitting-unit is the isolation unit, in which any suspicious case can be kept for further observation.

The children's ward unit in this building is similar to the maternity ward unit, except that the screens are of clear glass, permitting the nurse on duty to have close observation of all the children and still affording the necessary isolation. The large day-room, with airing-balcony, is also provided, together with the surgical dressing-room and other utility rooms.

CONCLUSIONS

After a careful study of the hospitals, after living in them and with them and after seeing the treatment given by the different doctors, there would seem to me to be certain fundamental essentials which every ward unit should possess; by this I mean every ward unit of a general hospital in which the surgical, the usual medical and special cases are treated or in which the majority of cases that come to us in this country are cared for. These essentials can be classed under the heads, (*a*) comfort of patients and (*b*) accessibility to service.

Comfort of the Patients.—The ward should not be overcrowded. Each patient should have at least 1,200 cubic feet of air, should be able to get the sunlight, yet should be protected from it when necessary. The ward should be provided with fresh air, heated in winter to be sure, but fresh, not roasted air coming from damp, confined cellars, but from outdoors. Above all, the wards should be ventilated, and this ventilation should extend throughout the twenty-four hours in the day.

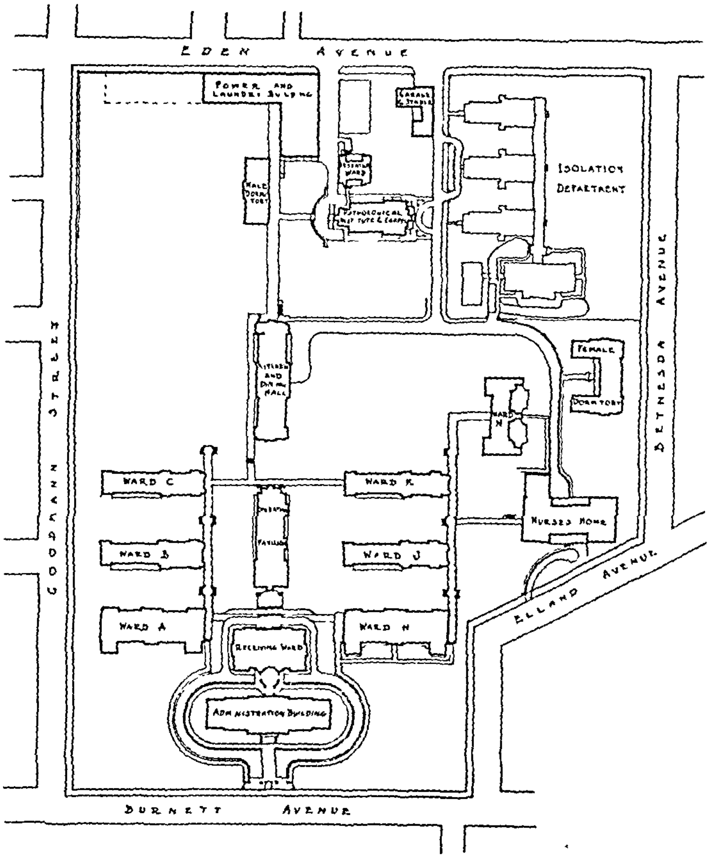

Fig. 6.—New general hospital at Cincinnati, block plan.

The patient should have semiprivacy and some place in which to hide the household gods which he may have brought with him and which are as sacred to him as some of our dearest possessions.

The lighting by day and night should be a subject of careful study. The patient's eyes should be shielded from the glaring light and a night-light should be provided, so obscured that the lighting of it for night inspection would not necessarily awaken the patients. It is my opinion that no direct ceiling light should be used, as a reflected light is much softer and more agreeable. There should be a bedside lamp, to be used for examination or for the patient's comfort in reading. Then, too, the windows should be so low that the patients, when in bed, can readily see out.

A resilient floor-covering adds not only to the comfort of the patients, on account of lack of noise, but to the comfort of the nurses as well. Linoleum, in its various colors and thicknesses, has proved a successful floor-covering.

The therapeutic effect of color on the patient is noticeable. The coloring of the lower seven feet of the wall with some warm shade, with perhaps a simple pattern of stencil above, gives the ward a cheerful aspect.

The addition of a few simple pictures (which can be removed from the walls daily for dusting) adds a little cheer.

Then the hardware should be thought of. How often is a patient awakened by the clicking of the latch! Why not eliminate the latch? Put a pull on the inside and a checking spring, and the noise is eliminated.

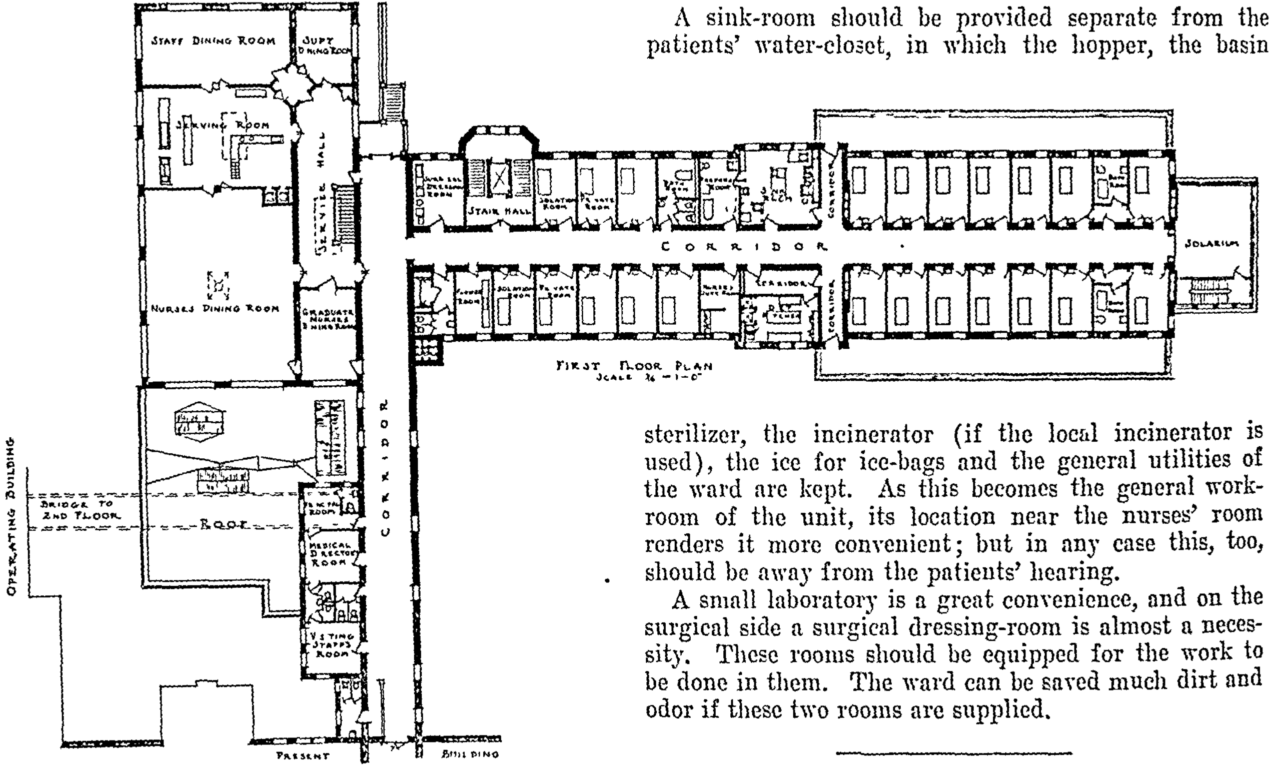

Fig. 7.—Harper Hospital, Detroit.

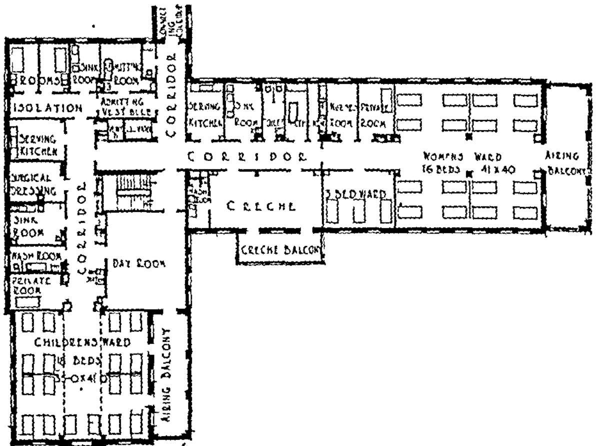

Fig. 8.—Maternity pavilion, Bridgeport (Conn.) Hospital.

The nurses' calls should be silent—lights, with perhaps a buzzer at the nurses' room, which would not disturb the patients.

Comfortable beds should be provided, with large casters for wheeling to the open air.

Provision should also be made for the comfort of the patient's visitor, with easy chairs, a table at which one may write a letter, etc.

Accessibility of Service.—Perhaps the most important thing is the serving-kitchen, to which the food should be brought hot from the main kitchen. This room should be of sufficient size to admit the various nurses and ward maids at the eating period. It should be equipped for necessary light cooking, for the keeping of food warm or cold, as needed, and, if necessary, for the cleaning of the china, for the convenient laying of trays, etc. Owing to the almost constant use and unavoidable noise of this room, it should be removed from close proximity to the patients' rooms, or should be provided with double doors.

A sink-room should be provided separate from the patients' water-closet, in which the hopper, the basin sterilizer, the incinerator (if the local incinerator is used), the ice for ice-bags and the general utilities of the ward are kept. As this becomes the general workroom of the unit, its location near the nurses' room renders it more convenient; but in any case this, too, should be away from the patients' hearing.

A small laboratory is a great convenience, and on the surgical side a surgical dressing-room is almost a necessity. These rooms should be equipped for the work to be done in them. The ward can be saved much dirt and odor if these two rooms are supplied.

ARCHITECTURE OF THE MODERN HOSPITAL FOR CONTAGIOUS DISEASES *

L. A. LAMOREAUX
MINNEAPOLIS

I hope that my paper may produce some discussion among members of the medical profession and possibly among the architects, because I am going to present a line of thought somewhat different from that which is usual on the subject of hospitals.

These institutions have followed the same line of development for centuries. They are being added to now and new hospitals are being built on the same principles that have been followed for the last hundred years. There are of course exceptions.

The United States is noted for its advancement in business buildings; we are the first country in the world in office buildings; New York is known the world over for its sky-line. Good contagious hospitals in the United States are the exception. That is, the contagious hospitals in the United States do not seem to have had the same amount of thought, care and money spent on them that has been spent on the general hospitals.

---

* Read in the Section on Hospitals of the American Medical Association, at the Sixty-Fourth Annual Session held at Minneapolis, June, 1913.

Dr. Herbert O. Collins, superintendent of the Minneapolis City Hospital, and I had the pleasure of inspecting the different contagious hospitals in the United States. In selecting the best and most modern of these I think that both Dr. Collins and I would have no hesitation whatever in naming the Measles Hospital of New York City. It is a building probably 125 feet long and six or seven stories high and has more of the modern requirements of a hospital than any other we saw; it has conveniences for isolating patients in wards, conveniences for treating patients as they are treated in hospitals known as cubicle institutions, solariums, porches, splendidly lighted rooms and a handsome building taking it all through, so that without question it stands out as the best of the contagious hospitals. All the rest are developed on the old lines, that is, are scattered over almost a ten-acre lot.

The prevailing idea of any one who has the building of a hospital in charge seems to be that a large tract of ground is necessary and that the buildings must be scattered all over this tract. This principle is noticeable in all German hospitals; some of them cover acres and include forty or fifty two-story buildings, most of them connected by long, expensive underground corridors—tunnels, you might say—and possibly some corridors above. In our country this plan necessitates unduly large heating plants and unduly large fuel bills. It necessitates the construction of a basement which is about one-third of the building and is of absolutely no use except possibly for storing a few mattresses. These institutions would be better off without basements in nine out of ten cases; and yet one-third of the cost of the buildings goes into them. A large portion then goes for covering all of these buildings with roofs, which is unnecessary. and, moreover, a large amount of expense must be figured in for maintenance of these roofs. There is also an unusually large amount of outside wall. In the East we find the cost of these institutions running up to $2,000 and $2,500 per patient. That is ridiculous and unnecessary.

If I were given the problem of constructing a municipal hospital, say one in which contagious cases were also to be cared for, and I had a piece of ground one block square on which to build it, I should consider that almost ideal for a moderately large hospital, say, one which would take care of 2,000 patients. I should divide the building and block in halves. I should so locate the building that the sun would reach all the rooms both forenoon and afternoon; that is, I should, if possible, put the axis of each building on the north and south line. On one-half of this block I should build a general hospital, and on the other half a contagious hospital. Between these two buildings I should locate the power-plant, the kitchen and the laundry. Those would be the only portions of the building that I would have separated from the remainder of the institution. I would construct this building as we are constructing office buildings to-day. Here in Minneapolis we would probably build it of concrete; in Chicago and New York they would probably use the steel and tile construction. For the present needs I should make it possibly two, four, six or seven stories high. I would construct the supports of a strength to allow for the development to any height to which the institution is likely to go, say twelve, fourteen or sixteen stories. There is no reason why a hospital building sixteen stories high should not be most convenient; for example, instead of traveling through underground corridors and tunnels from one building to another over several acres, it would be possible to step out of a business or administration office, take an elevator and go in from fifteen to thirty seconds to any floor in the institution, and this would be a convenience which it seems to me would be up-to-date. This plan has another decided advantage; it makes it possible to separate different classes of cases; the medical cases and surgical cases can be placed on separate floors, the operating-rooms can be isolated, and all these separate units are quickly accessible to any one; besides, this plan has the advantage of light which cannot be had in any other hospital, the advantage of pure air away from the dust, and the advantage of increasing the size of the lawn for the use of convalescents, a thing which is impossible if the ground is practically all covered with buildings. Taking it all in all, it seems to me that there is a future for hospitals which has really never been touched on or thought of in this country.

I wish to mention a few points in regard to the present contagious hospital which we are beginning in Minneapolis. We have too little ground considering the fact that the plan which I have just outlined was not developed from the start. We have two-fifths of a block on which we are now erecting buildings which will take care of probably a thousand patients and will also have among them a nurses' home. If the old portion of the building had not been started three stories high and spread out, the system which I mentioned could have been carried out. I should like to start the institution over again. The city council has shut off our appropriation excepting $25,000, which is enough to start the basement, and which we now have. We have also an appropriation of about $250,000 for the building, but we shall not get that this year. The contagious disease hospital, which we are now building, is T-shaped. The dimensions on the ground are about 120 by possibly 100 feet. There are open-air corridors between the sections of the T. In one section of the T we have the nurses' rooms, sleeping-rooms, one or two rooms for help on each floor and two elevators. Each elevator has a compartment by itself and runs up through the different floors and connects with the outdoor corridor. Thus, in a sense, it has no connection with the contagious part of the hospital at all.

The next section of the T is divided into private rooms and what we term the observation room. The private rooms each have a separate bath, and are constructed *en suite,* so that a patient and possibly a patient's mother or some attendant can occupy them. The observation room has a few distinctive features which we found in different places. For example, each room has a Dutch door—one that is cut in two in the center; the top half opens independently of the lower half. This allows the lower half of the door to be closed in order to keep a child patient inside of the room so that he will not annoy the nurses and spread contagion by circulating through this portion of the building. It also, of course, gives more air and opportunity for observation by the nurses. Adjacent to this Dutch door is a plate glass occupying the remainder of the front of the observation room. This also gives the nurse a chance to see what is going on in the room, and makes the room a little more cheerful, and possibly makes it appear larger. A lavatory is placed adjacent to the door, the intention being to treat the patients as much as possible as they are treated in the cubicle hospital. This makes it possible for a nurse to wash as she leaves the room. The lavatory is provided with a high faucet, or you might call it a spray, so that the arms can be easily placed under the spray at the time of the cleaning up; it is operated by a foot pedal. The doors of the hospital are operated by a latch so that the nurse can use her elbow in passing to and from a room if she so desires. Adjacent to this door is a space for hanging gowns. At the opposite end of each observation room (in order not to be obliged to construct separate baths for each room, making a very expensive plumbing bill) there are water-closets separated by marble slabs; across the front of each a curtain can be drawn, or, if we see fit, a door can be hung. This room is so arranged that a patient can be kept there for a period of ten days or more without being obliged to go into other portions of the institution.

The wards are in the third section of the T. These wards are small, accommodating not to exceed from five to eight patients each. In some hospitals that we inspected we found as many as fifty-one patients in a ward. This, of course, I know the physicians were not at all to blame for, but was simply due to the fact that they had not sufficient appropriation for buildings to take care of the patients. We found patients occupying both ends of the same bed, not only in one but in dozens of cases. I shall not discuss that further, however. Our wards are so divided as to accommodate from five to eight patients, as I said. They are also provided with glass screens of the kind used in the cubicle hospitals. A large number of the rooms will be so divided. The convalescents, of course, occupy the wards before they are passed out of the institution; consequently the solariums are connected with these wards. They are provided with casement windows to be closed in the winter. The solariums occupy the entire length of one end of the building, and each floor in the institution will have one, so that all the wards in the building will have access to them. They are about 10 or 12 feet wide and 40 or 50 feet long.

The second floor has been assigned almost entirely to pay patients. Being a city hospital, the institution has to take outside and pay patients as well as free patients.

A few of the general utilities, which, of course, ought to be in any up-to-date hospital, have been concentrated as much as possible in the center of this T. There are clean-up rooms opening directly into this, in which there are lavatories for the doctors and nurses; from these they must pass into the clean room and thence into the open-air corridor. These doors are so constructed that they cannot be opened from the inside; for example, when a person enters the soiled room, he cannot pass back into the institution, but must go through the clean room and open-air corridor and come out the other way. Thus indiscriminate running in and out through these rooms is prevented.

One of the other central features is a clean-up department for the patients as they go out. This constitutes a bath-room and a clean room, into which the patient takes his clothes and from which he goes into one of the elevators. It is our intention as much as possible to keep one of the two elevators clean and the other for the general use of the hospital.

Another feature in the central portion of this T is the diet-kitchen. This opens directly opposite the elevator and onto the open-air corridor through two windows; through one of the windows the food is passed in. There are no dumb-waiters in this institution, the intention being to use the elevator for bringing up food-cars. The food is brought to a point in front of the diet-kitchen and passed through one of these windows. The other window is intended for the passing out of utensils and pans which are necessarily returned to the general kitchen. It is the intention to return as few things as possible, keeping all the dishes of each floor in the diet-kitchen. When the utensils are sent to the general kitchen they pass through a sterilizer, which consists of boiling water inside of a large vat, arranged much like a dish-washing device. In the central portion of this T we also have a series of incinerators, one on each floor, above each other.

We are contemplating taking care of 300 patients in this way. The building is designed for thirteen stories. We are going to build eight stories at present and add to the building as it becomes necessary.

One other thing which seems to be quite essential. and which we found in but one contagious disease hospital in the country, is an alarm-bell. Each floor of our institution will have an alarm-bell, that is, a button covered with a piece of thin glass, which will necessarily be broken before an alarm is turned in. This alarm-bell will be rung in the rooms of the house-physician and, of course, is intended to be used in case of an emergency when a patient needs immediate attention.

Another feature which seems necessary in a city hospital is that visitors be admitted, even to the contagious department. We have provided on the center of this T a small visiting-room with plate glass between the air-corridor and visiting-room. This will permit of the bringing of a patient into the visiting-room so that a mother, for instance, can see her child without being infected or coming in close contact with it. The hospital is arranged so that live steam can be turned into several of the rooms on each floor.

The institution has four or five admitting-rooms. These are just as small as possible and are designed and finished with the idea of making the room sanitary. easily cleaned and easily fumigated. They connect directly with the elevator.

Besides the clean-up rooms on each floor, which are intended mostly for doctors' use and for nurses passing in and out and going to the dining-room, etc.. there are general clean-up rooms in the basement. The basement is well above the ground so that it will be reasonably light. These clean-up rooms are for the doctors, nurses and male and female help. Here they have lockers in which their clean suits are kept and they can thoroughly clean up when they are going to leave the institution.

In the basement there is also one large diet-kitchen with all the conveniences of a hotel kitchen; there are lockers which will take care of the clothing of the entire institution, a sterilizing room and laundry. The laundry is divided into two sections.

The clothes-chute, which reaches a balcony from each floor, opens outside and has no connection whatever with the inside of the building. It is also open like a flue to the top of the building. It is so arranged that it can be sterilized and washed with hose. This clothes-chute opens into that section of the laundry into which the soiled clothes are first sent; it is separated from the clean portion of the laundry by a solid partition; sterilizing tubs, running under high pressure, are placed half in the cleaning-room and half in the soiled room, thus permitting the clothes to be placed in the water, sterilized and taken out in the clean room; from here they are sent to a general laundry.

The motors for running the elevators, a morgue and a chapel are also in the basement. The chapel cannot be reached directly from outside; persons entering the chapel are required to pass through the office of the institution.

CONCLUSIONS

As arguments for a high building I would mention economy in the purchase of ground; good air above and freedom from noise and dust, quick access to all parts, economy in plumbing installation and in the fuel bills, saving of time of doctors going to and from the institution, ease of getting clothes to the laundry and ease of getting hot food to the patients.

For many of the ideas which I have mentioned I am indebted to the superintendents of hospitals; for example, Dr. Hornsby of Chicago, Dr. Place of Boston, Dr. Richardson of Providence and Dr. Wilson of New York.

ARCHITECTURE OF THE GREAT CHARITY HOSPITAL*

RICHARD E. SCHMIDT
CHICAGO

The large charity hospital, which must handle a great many patients at the least possible cost and give them the largest possible measure of intelligent care, should be arranged architecturally so that the physicians, nurses and the common employees can do the greatest amount of work with the least expenditure of time and energy.

These principles have guided most hospital architects and the difference in the arrangement of these great plants in different institutions is due to the valuation by architects of the respective services.

I shall try to picture the ideal institution of this character:

1. The administration department is naturally the gateway to such an institution; it is, therefore, the first building that we enter; the offices are there; the information bureau is there; all business with the outside world is conducted there. It should therefore be convenient to reach.

2. A division of the administration department of the institution is the admission bureau with its examination rooms, its dispensary, or outpatient department, its baths for the admission of patients, its clothes-lockers, and, since all clothing must be sterilized before it is put away, its clothing sterilizer. This business of sterilization is quite a technical one under modern-day methods, including the handling of steam machinery, and should be in the hands of experts. Dressings of all sorts and various materials that go to the operating-rooms and to the surgical dressing-rooms must be sterilized. These materials must go to all units of the hospital, however many there are and wherever located, and it would seem an ideal arrangement to have the whole sterilization plant at one place where it could be under the control of people who are doing nothing else but that work, so that it will be done expeditiously, economically and methodically. Thus, the whole sterilization plant would become a unit of this admission bureau.

3. The stores of the hospital, whether papers of pins or cars of coal, must be receipted for by the responsible storekeeper, and these stores are subsequently distributed to all parts of the institution. It would seem, therefore, a good plan to have the storekeeper's office and his store-rooms located at some central point, and as that officer is a part of the business administration of the institution he belongs somewhere in the neighborhood of the administration bureau.

4. Modern humanitarianism is demanding more and more all the time for the convenience, comfort and care of those unfortunate members of society who cannot help themselves, and especially is this true of the sick poor. One of the greatest factors in the comfort of these people is good food, properly, quickly and intelligently served. This means that things which should be hot should reach the patient hot, and things which are intended to be served cold should reach him while they are still cold. We have already suggested that the stores should be at a central point for better distribution, meaning ice, milk and vegetables, as well as the surgical and medical supplies and the household materials, and if to keep these stores at a central point it will add materially to the economical administration of the institution if we have the kitchen and serving-rooms near by.

We have, therefore, another unit added to those which I propose to locate centrally. In many places, especially in the large institutions of Germany, steam or electric trains carry the food from some remotely located kitchen to the various points of distribution in the wards. Experience has taught us that, while these trains are economical and efficient, as to the physical work of transporting food, they are not entirely satisfactory from the point of view of the patient, as the food does not reach the sick in an appetizing and palatable condition. It would seem that a better plan would be to have the kitchen so centrally located that the food could be rushed in an appetizing condition to even the remotest point of distribution.

5. The pathologic department of an institution has come to be recognized as one of its most important factors. The morgue is a part of this unit, with ice-boxes, necropsy rooms, which should be well lighted and comfortable as to temperature and ventilation, and, if there are students to be thought of, and especially if there is a school connected with the institution, a small, well-arranged amphitheater. As all dead bodies are brought to the morgue, it becomes necessary to place on view there the unidentified dead; for this reason a chapel also becomes a part of the pathologic unit, in which services can be held over the dead; this is especially necessary with the poor, who are the sole patrons of these institutions. Many of these cases must be passed on by the coroner; therefore, there must be an inquest-room with witness-rooms adjoining. There are perhaps some objections to having all this array of rooms in direct connection with the laboratory of pathology, but it is inconceivable that the morgue and necropsy rooms should be at a distance from the pathologic department when, as a matter of fact, the moment that breath leaves a human body that body at once becomes a pathologic specimen and, when a necropsy is to be done, is turned over to the pathologists, and since where the dead body is, there must also be the coroner, his witnesses and jurors and the chapel for the last rites for the dead.

In this day most large institutions are fitted in the various units with small auxiliary laboratories in which the simpler pathologic procedures, such as urinalysis, blood-counts, blood-pressures and smears of various sorts identified under the microscope, can be carried on. Many of the simple procedures, however, become complicated at certain stages and the facilities and perhaps the more expert knowledge of the central laboratory must be invoked for an efficient settlement of mooted questions. The central laboratory should, therefore, be so located as to afford ease of access from the auxiliary laboratories in the various units of the institution. Then, too, there are vaccines to be given which are kept in the refrigerators of the central laboratory because the conditions under which they must be kept are exacting and their repository must be carefully watched for correct temperatures. There are autovaccines to be made; these autovaccines must be incubated under carefully directed conditions, in carefully regulated incubators, and the technic of their preparation is most exacting; hence they are always made in the central laboratory. There are serums to be prepared and administered in almost every unit of a general hospital. In the children's department, in the lying-in bureau, in the surgical and medical wards and in the infectious disease quarters, as for instance, the antimeningitis serum and the diphtheria antitoxins.

---

* Read in the Section on Hospitals of the American Medical Association, at the Sixty-Fourth Annual Session held at Minneapolis, June, 1913.

One can see how necessary it is, therefore, that the pathologic department shall be centrally located to save time and expense in energy.

6. If there is a school or if there are lecture-rooms for large bodies of students, they should also be centrally located because often the material to be used before the classes will come from many points in the institution, and the closer by these points are, the better it will be for patients. Of course, there will usually be small clinic-rooms for small numbers of students. located in the various units, where one or two patients can be examined at a time by half a dozen students under the direction of a demonstrator or clinician.

7. It will depend on many conditions whether there shall be one operating department located centrally, or whether there shall be a number of surgical operating-rooms, each one located at a point convenient to a particular class of patients; as, for instance, one operating-room in the children's department, one in the gynecologic department and often one in the obstetric department; and in the large institutions there is also a genito-urinary department, for many surgical cases of this class are highly infectious. There is much surgical work to do even in the obstetric department—cesarean sections, pubiotomies and the ordinary post-partum repair work. In tuberculosis some of the most satisfactory treatment is now surgical; in tuberculosis of the bones and joints, for instance, and in active tuberculous processes in the intestines or pleura. There is often a certain amount of brain-work that can be done for tuberculous patients nowadays. In fact almost every department of the hospital supplies its quota to the surgical operating-rooms. The medical profession is not agreed for or against a centralized operating-plant. The cost of administration when the plant is divided into an operating-room for each class of patients is exceedingly high. Nurses and interns must be kept on duty whether or not there is work to be done. The apartments must be maintained in an aseptic and scrupulously clean condition, which takes a vast amount of work compared with the small amount of operating. Some physicians insist that it will not do to bring venereal cases into an operating-suite in which clean surgery is done and in which gynecologic cases are infected on their admission: some general surgeons object to having these cases brought into clean quarters. On the other hand, the advocates of a central operating-plant insist that no case should ever be brought to any operating-room until it is surgically clean and that the vilest venereal operation may be quite as clean as the operation for a ruptured appendix. Eventually the surgeons and medical staff of the institutions will probably be called on to determine whether their operating department may be centrally located in the interest of economy and efficiency as a whole, or whether they prefer to take the hazards incident to a large number of operating units located at widely different points and perhaps maintained under less careful supervision than would be the case in a central plant. It seems to be admitted that prompt, quick and careful transportation of patients even over considerable distances, as, for instance, from one building to another, is not trying on the patients and is not hazardous, as a rule, and in some places recovery-rooms are employed to hold patients until they are in a condition to be moved back safely from the operating-rooms to their own beds.

I have now pretty exhaustively covered the group of units that I think should be located in a central area, easily reached from all parts of the institution. The transportation for everything in connection with this layout can be done through well-lighted and well-ventilated tunnels underground, running through the basement of each building, and these tunnels can also be used for carrying the pipes for the physical service of the whole institution. The tunnel, for instance, can be 16 feet wide by 7 feet high. Nine feet of this tunnel can be used for passenger and freight service and a separate wall can be built up to separate the pipe tunnel from the other structure. The whole tunnel can be made of reinforced concrete, including the dividing wall and the roof. On each side of the pipe tunnel hooks or hangers can be placed, and if 2 feet on each side of this tunnel are taken for pipes, 4 feet will be left for a passage and workway, and this tunnel will contain all necessary pipes for heating, refrigeration, hot and cold water, electric conduits, etc., that are necessary for institution service. Arranged in this way they are easily accessible for repairs, or renewals or any changes that may be required. The passenger and freight part of the tunnel need not be elaborate. A solid concrete floor with smooth finish can be made to answer every purpose, although terrazzo or some of the monolithic or tile floors add to the appearance of the tunnel. The walls can be waterproof cement, white enameled, with a glazed finish, or they can be made of vitrified glazed tile, which is far costlier. The roof can be made of waterproof cement with a glazed finish, white enameled, or treated in any other desired way. Ventilation can be had by air-ducts at intervals, or the whole tunnel can be ventilated by running a shaft into the general ventilating shaft of the institution or by allowing the top of the tunnel to be a few feet above ground with small transom windows for both air and light.

If this general plan is carried out, elevators will be necessary in every building which communicates with the tunnel and is intended to be a part of the general service, but automatic, electric and hydraulic elevators are being made so efficient at present, (and "fool-proof") that they can be regarded as perfectly reliable. Although the cost of installation is a little higher than that of the man-operated elevators, the up-keep is low, as they do not require an elevator man to each car.

There are certain administrative units that will not be required as a part of this central area.

1. The mechanics or transmission of water, steam and electricity are so efficient that the refrigeration, ventilation and steam and electric service of the institution can be conveyed over considerable distances with comparatively little loss of efficiency. If the steam and refrigeration pipes are well covered, and if the electric service is well insulated and the whole transmission system is well installed, there is no good reason why the power-plant should not be located at the outskirts of the land area of the institution where the noise of the machinery and the smoke and dirt will not interfere with the established order of things in the institution proper.

2. The laundry is in reality a part of the power-plant of the institution. It requires immense quantities of hot water and live steam. It deals with complicated mechanism that should be under the control, operation and guardianship of the engineering department. The laundry should therefore be immediately adjoining, or a part of the same building with, the power-plant and there is no good reason why this should not be the case. It is not very much trouble and takes very little time to transport a cart of soiled linen three hundred feet more or less, or even a quarter of a mile, because large loads can be hauled. An ordinary depot truck with rubber tires and electric motor can be used for the purpose if desired. These are made most efficient now and are in use in all the large depots of the country. They move rapidly, pull large loads and are easily handled. Automatic elevator service can be employed if necessary to locate the laundry over the power-plant and excellent administration technic can be employed for the handling of soiled material into the laundry and clean material back into the building through the tunnel. In most institutions heavy canvas bags, which prevent the spread of infections, are used for the soiled linens and these serve to save the goods from rough handling at the hands of the help. Even the linen-rooms can be located in the laundry if desired, and there is no particular reason why they should not be.

3. The incinerators for garbage from the kitchen suite, which will be vastly greater in quantity than the refuse from any other single unit, can be destroyed either in the fires of the power-plant or in an incinerator near by which will feed its smoke into the regular power-plant used. In most large institutions incinerators are being installed in the walls of the slop sink-rooms of the various units, for the destruction of garbage, dressings, etc., from those units. This system of destroying garbage in the various units will grow in favor and will come finally to be universal if the makers of these mechanical contrivances can devise a plan that will not render their use too costly in gas consumption.

ABSTRACT OF DISCUSSION

ON PAPERS OF MESSRS. STEVENS, SCHMIDT, LAMOREAUX AND HORNSBY

DR. CLEVELAND H. SHUTT, St. Louis: One of the speakers made the point that the European idea of hospital construction has developed largely in the direction of spending much money in covering a large area with low buildings and not affording bed space proportionate to the expenditure for the care of patients. I believe that it is reasonable that we should care for the greatest possible number of patients with a due regard to expenditure.

Nearly all of our cities provide free hospital facilities and many of them provide some opportunity for pay patients also. Each city has a certain revenue annually, and out of that revenue various departments must be maintained. Those who have been in public hospital work have difficulty in obtaining the necessary funds for conducting and erecting institutions. Aside from the justice or injustice of the situation, it is the actual condition with which we have to deal. An institution erected on the story plan, for a public hospital, is more economical in maintenance and in the original cost

The paper regarding hospitals for contagious diseases interested me much, because in St. Louis we are just preparing to erect such an institution. We have adopted what might be styled the unit system—a separate unit or building for each of the more important diseases, scarlet fever, measles and diphtheria, and one other building for miscellaneous contagious diseases like whooping-cough, chicken-pox and erysipelas. Each building is also arranged for sectional isolation. Our aim has been to isolate everything connected with one disease. Everything coming from a building will be sterilized before it leaves it, including the laundry, food and utensils. There will be incinerators, steam sterilizers and utensil sterilizers in a service-room at the entrance of each building.

There will be a one-story isolation building having sixteen units under one roof. It will really consist of sixteen little houses under one roof with a corridor between, affording air on all sides. We have made some improvements on the Philadelphia plan by providing a small room in each of the units for a nurse to live in, with a glass wall to give her opportunity to observe the patient at all times.

We are not providing a building for private patients, profiting by the Philadelphia experience that there were not sufficient patients to justify the maintenance of the building further as a private building. We are having rooms constructed in the main building so arranged that they can be utilized for private patients.

DR. JOSEPH B. HOWLAND, Boston: The use of incinerators in individual wards is, it seems, becoming general, although it is likely to be expensive. At the Massachusetts General Hospital all ward refuse, whether garbage or dressings, goes back to a central room and is inspected. The result of those inspections has shown that it would be expensive to allow the nurses and help to burn up anything that they thought might be disposed of in the ward.

Garbage inspection shows how much garbage is coming from an individual ward, which may indicate that the nurses are serving entirely too much food. It also gives us a clue to the fact that certain foods are not being eaten well; it gives us a hint that may be useful in the kitchen. We also find things that should not be there. Then in the disposal of our dressings we find all sorts of extravagance. If those dressings are burned, safety-pins, rubber tubing and many things that could be used again are destroyed. I cannot see any good in incinerators in the wards except in a contagious hospital, perhaps. I have had no experience with them. I think that the plant should be centralized and all that waste should be inspected before it goes to the incinerator.

DR. CLEVELAND H. SHUTT, St. Louis: We have one building with sixteen isolation units. It will be arranged so that we can isolate any disease in that building, and isolate an entire family with a nurse in the room, if desired. That is where we expect to treat the menace infection.

In each main building there will be two rooms that can be sterilized at any time. If a patient should be in the measles ward and develop diphtheria, as soon as this is suspected, he will be moved into the isolation room.

DR. E. E. MUNGER, Spencer, Iowa: I can hardly agree with everything that Dr. Hornsby has said in his paper as to remodeling an old residence to make a place in which a man can do good work. A man can do good work in a kitchen with proper assistance. There is one serious objection, however, to the establishment of many more small private hospitals, whether made by remodeling old buildings or with new bricks. We have quite a supply of small private and so-called public hospitals, and too many of them are the outgrowth of a desire to further personal and selfish (if not sometimes ulterior) interests. Some of these small hospitals are about the least concerned with the public welfare of any quasi-public institutions with which I am familiar. Judging from common comment they are fairly remunerative on the side of selected surgical cases, while on the hospital side they are flat failures. They do not favor that professional harmony which makes for cooperation and resulting benefits. On the contrary, they foment discord, jealousy and conflict among medical men and encourage general dissatisfaction and suspicion among laymen. They do more than this: They make it easy for competitors not recognized in these private hospitals to refer their patients elsewhere to whomsoever they will, with or without a division of fees. This occasionally reacts on the proprietor of a small private hospital, who in turn is forced to the wall, or worse. Many more small private hospitals are not needed. I would not have these remarks construed to mean that there are not many capable men who are struggling to maintain hospitals for the benefit of the public. There can be no doubt about this, but these same men could render a much greater service to the public and be themselves more justly rewarded were it possible for them to serve the public through a public hospital and be relieved of the cares and anxieties incident to the business side of their undertakings. I called the attention of this section a year ago at Atlantic City to the effort we are making in Iowa to remedy some of these things and provide hospitals for the people along the lines which have been indicated showing what they are doing for the people in a corporation community.

Dr. F. W. Robinson, Sturgis, Mich.: I live in a town of five thousand population and own a private hospital. Every physician in the town is interested in the hospital and takes a personal interest in the standard of work done and the prosperity of that institution. I am somewhat surprised that in these papers the corporation hospital has not received more attention. Most of our hospitals, in our cities especially, are located on noisy street-car lines with the idea of getting the hospital centrally located and easily reached. Now one block or three blocks or ten blocks amounts to nothing as compared to the comfort of a patient. I believe that the time is coming, and it is not far distant, when we are going to see our patients receive better care. I believe that each hospital should be so constructed that each room will open onto a screened porch, so that the bed can be pushed right out of the door onto the porch without having to be dragged along a long hall.

I disagree with Dr. Munger on the question of the small hospital tending toward poor work. I believe that the small hospital tends toward good work. Two small hospitals which I know, one in our town and one in another town, are doing good work, and instead of driving the physicians apart they are pulling them together. At one time no two physicians spoke to each other. To-day three of them own an automobile and all of them attend the meetings. Now the hospitals work together. In the other town the hospital has only been in operation one year and I can already see the benefit to that town of drawing the physicians together. If the hospital does separate physicians in a town it is because the physicians are at fault, not the hospital.

Dr. John N. E. Brown, Detroit: This discussion ought not to be closed without a protest against the remarks made or the impression given by two or three of the speakers who have been advocating the skyscraper hospital. Sir Henry Burdette, the greatest living authority on hospitals in England, after having given fifty years study to this subject, is advocating a hospital city. That is to say, he believes in taking all the sick outside the city and having them looked after there by doctors and nurses, where they will have the best chance of recovery.

I am of the opinion that the German system of construction is cheaper than that of this country. Most of these spread-out hospitals are built of a cheap brick covered with stucco on the outside, because the Germans have felt that in the course of twenty years from now it may be necessary, as has been the case in the last twenty or thirty years, to materially change the construction of hospitals.

One point that Mr. Stevens brought up was the admitting unit. He showed, in the Munich-Schwading Hospital, three rooms for the admission of patients. Of course, the practice varies in Germany. In the hospital in which we are interested we are just considering the problem of the admitting rooms. I noted with interest this morning in looking over the city hospital here that is just being built by Dr. Collins and Mr. Lamoreaux that they are making an admitting department which will accomodate thirty patients. These patients will be held there for twenty-four hours before being sent on into the hospital.

Then there is the matter of sink or utility rooms being placed near the entrance to the cross-corridor. I have found nurses objecting to that. They prefer the utility rooms somewhat more at the end of the corridor, especially in private-ward pavilions, so that they will not meet so many people coming to and from the hospital near the entry while carrying bed-pans. If the utility rooms were placed more remote from the center of the corridor it would be much better.

Then the question arose about putting the utility rooms, as shown in the Munich-Schwabing Hospital, on the north side of the ward. The query arises whether or not the sun is not as necessary in any utility room or diet-kitchen or servant's rooms as it is in the patient's bedroom. These rooms are subject to infection from bed-pans, dressings, and so on. We know that the sunlight in two hours will kill the pathogenic organisms, therefore why should we not place our utility room so as to get the effect of sunlight?

Dr. H. B. Howard, Boston: When you build the skyscraper hospital, there are two or three things that you must consider at first that were not mentioned by the speakers so far as I know. When you put a building fifteen stories high on the edge of your own lot you must recognize the fact that somebody across the street some day may put up another building just the same height. So it is not safe to build to any great height, except in the center of your own lot; then you will have the advantage of the street and the rest of your lot. It is not safe, then, to use the lower stories for patients. You will find that in the hospitals in which there are many stories the lower stories are used not for patients but for offices and for the business part and for the housing of the employees. When you get above the surrounding buildings you can count on sunlight for your patients. It is wrong in building hospitals many stories high to place the patients' rooms where they are not going to have the sunlight. In contagious wards the sun is needed more than in any other part of the building.

Mr. Richard E. Schmidt, Chicago: I do not agree with Mr. Lamoreaux that buildings become cheaper as you go up. You will readily see that the same floor load in a high building is carried over and over again on a column; the same floor panel in a sixteen-story building is carried one hundred and thirty-five times for the sixteen floors, whereas if it were only a one-story building it would only be carried once. The cost of the columns is consequently increased considerably. We know that two, three and four story masonry buildings in which the walls support the floors without the necessity of introducing skeleton construction can be built at prices ranging around twenty-five cents a cubic foot, and that a sixteen or twenty story building will cost almost twice as much.

High buildings are not cheaper than low buildings of the same capacity, for if cost of building became cheaper as the height of the building increased, there might be a point somewhere in the blue sky where the building would cost nothing.

I have noticed drafts in high office buildings, sometimes strong enough to blow papers from the table and slam doors when I could not find an open window. This has been especially noticeable on holidays when practically all of the windows were closed. At such times drafts in a high building will rise from the lowest floors and out at the top as through a chimney, and I found that an open door or window in a lower story and an open window in some remote place in an upper story would be sufficient to draw air through the building by circuitous passages. This appears to be positive proof that foul air will travel a much greater distance inside of a high building and subject more persons to its bad effects than can be the case in a low building.

Mr. L. A. Lamoreaux, Minneapolis: In regard to the cost of building, I think that when Mr. Schmidt has looked into this matter of construction he will quite agree with me. For example, in such buildings as the Johns Hopkins Hospital, in which they have but one floor and a high basement, the cost is as much, or even more, to build the basement as to build the hospital proper. Again the cost of additional land on which to spread out a hospital will more than offset the additional iron that is required to make the columns of a building strong enough to go higher. We are now building concrete office buildings here thirteen stories high that cost twenty-three cents per cubic foot and that will compare favorably in cost with a hospital building in which but half of the structure is used for hospital purposes.

SULPHURIC ETHER LAVAGE IN INFECTIONS: THE SOULIGOUX-MORESTIN METHOD

A PRELIMINARY CLINICAL REPORT OF THIRTY CASES TREATED BY THIS METHOD

GEORGE DeTARNOWSKY, M.D.
Surgeon to the Cook County and Ravenswood Hospitals
CHICAGO

Recently, while visiting the Paris clinics, my attention was called to the use of ether lavage of the peritoneal cavity in acute infections of the abdominal and pelvic viscera. Five of the municipal hospitals were using ether as a routine measure in all laparotomies. Morestin, surgeon to the Hôpital Tenon, reported his experiences with ether at a meeting of the Société de chirurgie, Feb. 12, 1913; Souligoux, surgeon to the Hôpital de la Charité, made a similar report Feb. 19, 1913, before the same society. On May 21, June 4 and Oct. 22, 1913, additional reports were sent in confirming the earlier experiences, not alone from Paris, but also from provincial hospitals.[1]

That the Societé de chirurgie should have discussed the same subject five times in nine months speaks for the interest aroused by this at first seemingly rather startling procedure. It was my privilege to watch the *modus operandi* of this lavage, and to observe the total absence of unfavorable sequelae. I began using ether in my abdominal operations in the latter part of August, 1913, on both private and charity patients. In a series of about thirty cases observed and recorded, the clinical results have been uniformly gratifying. Dr. Bissel, pathologist to Cook County Hospital, has undertaken an experimental study on animals which will appear in a later report.

Having used ether for the past eight years as a local disinfectant in the treatment of a large series of electric burns, I had already become firmly convinced that it had no deleterious effect on cell regeneration. It was therefore gratifying to find that Souligoux and Morestin, working independently, had not only arrived at the same conclusion, but, going a step further, had dared to use ether on serous surfaces.

HISTORIC EVOLUTION OF THE METHOD

I cannot do better than to quote Souligoux's own words. He said:

> I have used ether locally since 1891. At that time, while I was intern in the receiving-room, a man was brought in one day with both legs crushed by a heavy wagon. Both limbs were a mass of broken bones and torn tissues. I advised an immediate double amputation, which was energetically refused. Following this refusal, I cleansed the wounds the best I could with soap and water, poured an abundance of ether over them and placed both legs in plaster troughs (*gouttières*). To my utter surprise no infection occurred and the patient kept his legs.
>
> From this time on I washed all wounds in ether and used ether in all superficial infections such as abscesses, lymphangitis erysipelas, etc. In my treatment of lymphangitis of the arm, for instance, I would wash the limb with soap and water, wrap around it gauze soaked in ether, and apply gutta-percha, cotton and bandages in order to minimize the evaporation. Several hundred cases have thus been treated with uniform satisfaction. I also, in 1891, experimentally used ether in the peritoneal cavities of guinea-pigs, without any ill effects, but did not dare experiment with man until last year.
>
> In July, 1912, I was called to see a case of intestinal obstruction of eight days' standing. No feces or gas had been expelled for forty-eight hours. Examination revealed a complete rectal stenosis. The patient was in a condition of general peritonitis. I made an ileac incision, thinking to perform a Littré. On opening the peritoneal cavity there was free escape of gas and fecal matter. A median incision was then made and a perforation of the cecum found and closed. A general plastic peritonitis was present. Believing the patient to be moribund, remembering my experiences of 1891, and knowing that Morestin frequently used ether in abdominal operations, I poured an abundance of ether in the peritoneal cavity, carefully sponged it out and closed with two small drains. An inguinal colostomy completed the operation. The patient made a remarkable recovery, and since that time I have used ether in the presence of pus.

Up to Oct. 22, 1913, Dr. Souligoux and his associate, Dr. Marcelle, had reported thirty-six cases in which ether has been used as lavage. As much as 1 liter (quart) of ether has been poured into the peritoneal cavity "immersing the peritoneum in ether"; it is then swabbed out before the cavity is closed. In this series are 6 cases of ruptured tubal gestation, 17 cases of strangulated hernia, 3 cases of abdominal contusion with ruptured intestine, 1 rupture of stomach (ulcer) operated on twenty-seven hours after the rupture had occurred in the presence of general peritonitis, 3 cases of general peritonitis (origin not stated), etc. In this series two deaths are recorded, neither traceable to the use of ether.

Morestin's opinion is still more emphatic. He says:

> I have used ether since 1901 in peritoneal infections, either as a preventive disinfectant after suppurating salpingitis or in intestinal operations in which the bowel contents may have leaked, or as a curative method in grave cases of peritonitis due to (perforating) ulcers of the stomach or duodenum, or to acute appendicitis.

Auvray[2] reports the case of a man, aged 50, with a strangulated double inguinal hernia, with perforation of the intestine and general peritonitis. He closed the perforation, poured 1 liter of ether into the peritoneum, sponged it out and closed the incisions. He stated that he had never seen a patient, in similar serious condition, heal so rapidly. M. H. Toussaint[3] refers to the method as the *merveilleux lavage à l'éther.* Broca, Témoin and Patel (of Lyons) express themselves with equal enthusiasm.

---

[1] Ann. de la Soc de Chir., Paris, Feb. 12, Feb. 19, Feb. 25, June 4, Oct. 22, 1913.

[2] Auvray: Semaine méd., May 21, 1913, p. 248.

[3] Toussaint and Morestin: Semaine méd., Oct. 22, 1913, p. 515.

One cannot help but see in this method a precious ally, and consider ether as the best antiseptic of the peritoneal cavity. While I do not wish to exaggerate the importance of this practice, it is interesting to call attention to it because it offers few inconveniences and does not necessitate special precautions.

TECHNIC

After removal of pathologic tissue, free pus is carefully wiped out; then ether is freely poured into the abdomen and is allowed to come in contact with all of the viscera in a case of general peritonitis. The viscera are literally washed in ether, hence the term "lavage" adopted by the French. As much as a quart of ether has been thus used. After having remained in contact with the abdominal organs for from two to five minutes, it is mopped out by means of gauze sponges and the abdomen is closed with one small drain. In circumscribed peritonitis, the pus cavity, having been wiped out, is filled with ether and the abdomen is closed without drainage. In pelvic peritonitis, ether-soaked sponges are applied to all involved surfaces and then two ounces of ether are poured into Douglas' pouch and the abdomen is closed without drainage. The immediate effect of ether, thus applied, is to cause a momentary capillary contraction followed by hyperemia of the viscera. There is a moderate formation of carbon dioxid in the abdomen, evidenced by a bubbling sound and the escape of bubbles from the surface of the ether. Ether is slowly absorbed by the serosa; this is proved by the fact that no change in the anesthesia of the patient has been reported to date.

In my first three or four private cases, I requested the anesthetist to stop giving ether for five minutes, after using it in the abdomen. This is unnecessary and has been discarded. The postoperative course is comparatively painless. Patients remain for from six to twelve hours in torpor, with slow, deep respirations and a strong, slow pulse. Postoperative emesis is less frequent.

Morestin emphatically declares that ether acts as a local antiseptic; that it does not damage the serosa, does not lead to the formation of adhesions and has a beneficial tonic and anesthetic action.

To the foregoing reports I can add the personal experience derived from a series of thirty cases with operation at the Cook County and Ravenswood hospitals since Aug. 25, 1913. There was no mortality in this series. There were three cases of gangrenous appendicitis with general peritonitis, four cases of localized abdominal peritonitis, two of pelvic peritonitis and one case of acute cholecystitis with adhesions in which the bactericidal value of ether lavage appeared convincing. The remaining cases, in which the presence of acute sepsis was not marked, were classed as suitable for the prophylactic use of ether. In 75 per cent. of all my cases the immediate postoperative pain and restlessness was certainly diminished; it was normal in the remaining 25 per cent. Contrary to Morestin's experience, a primary stage of excitement was noted in only one case, an interval operation for a retrocecal appendix with Jackson's membrane in which operation was performed at Cook County Hospital, Nov. 22, 1913 (Case 527784). This patient was mildly delirious for twelve hours, but otherwise made a normal recovery. In only three patients did I use any drainage; all three were cases of general peritonitis; the remaining ones were closed without drainage, 2 ounces of ether being left in the peritoneal cavity.

CONCLUSIONS

Clinically, so far as one may judge from the rather limited number of cases observed, the method is a beneficial one; no deleterious effects were observed, and, in my private cases, close personal observation convinced me that, after ether lavage, there was less pain and less emesis than is ordinarily encountered in laparotomies. That ether does not injure serous surfaces must be conceded. Souligoux satisfied himself on this point in 1891, but unfortunately did not publish the result of his observations; clinically, no adhesions have resulted from this method. Should the combined experimental and clinical results coincide, it would seem to me that ether lavage will have to be recognized as a valuable adjunct to our surgical technic.

31 North State Street.

AZOTURIA (DIABÈTE AZOTURIQUE)

ANTHONY BASSLER, M.D.
NEW YORK

Robert Willis[1] observed "a peculiar morbid state of the renal secretion characterized, not only by a considerable increase in the quantity of fluid elaborated, but a great increase in the quantity of urea it holds dissolved, in some cases to be permanent and habitual." To quote him further, "This is another of the morbid states that has been described under the name of diabetes or diabetes insipidus. I believe it to be the common precursor or recent inquiries have shown it to be the general attendant of mellitic diabetes, as well as the state into which that formidable disease passes under the influence of treatment of a certain kind." Although the preceding was advanced in 1838, practically nothing is known of the condition in America. The library of the New York Academy of Medicine does not contain mention of it in a work of any kind or even a reprint on the subject by an author in this country, and such as there is on hand, which is meager and scattered, has been contributed entirely by the French and English writers. When one considers the broadcast interest in metabolic disturbances in this country and the fact that these cases exist among us, this seems strange.

According to Allbutt and Rolleston,[2] the term "azoturia" was applied originally by Prout to a condition of urine characterized by the presence of urea in excess, though Prout did not distinguish between the increase of urea and the other solids. Although he pointed out that it often preceded diabetes mellitus, he obtained little clue otherwise to its nature or pathology.

After the contribution of Willis, the condition was studied by Falk, Bouchardet, Lancereaux, Bouchard, Lecorché, Lasègue and others, an excellent monograph on the subject being contributed by Demange[3] with a review of the publications dealing with the condition.

CLASSIFICATION

Robert Willis divided the cases of diabetes insipidus into three groups:

1. Cases of hydruria. Those attended with an excessive discharge of aqueous urine, in which the solid matters are hardly affected.

---

[1] Willis, Robert: Urinary Diseases and Their Treatment. London, 1838, Section 3, p. 18.

[2] Allbutt and Rolleston: System of Medicine, Vol. iii, Diseases of Obscure Origin, London, 1909, p. 226.
Delaunay: Gaz. hebd. d. Sc. méd., April, 1913.

[3] Demange: Paris Thesis, 1898, Dechambre's Dictionary, Article on Azoturie.

2. Cases of anazoturia. Those attended with a copious discharge of urine with a deficiency of urea.
3. Cases of azoturia. Those in which the excessive discharge of urine was accompanied by a superabundance of urea.

The preceding classification recognizes azoturia as a subdivision of what has long been designated as diabetes insipidus, and it is now recognized with azoturic conditions that this classification has outlived its day and cannot be considered as important in this connection. The same may be said of Ballet's classification offered in his discussion of Mathiew's case of diabetes insipidus in an hysterical patient (simple polyuria, without azoturia or phosphaturia), namely:

1. Simple polyurias, with stigmata of degeneration (physical and psychical).
2. Simple polyurias, *with stigmata of hysteria*, without stigmata of degeneration.
3. Azoturic polyurias, with stigmata of hysteria.

These are the only classifications on record in which the term "azoturia" appears, and as a proof of their deficiency to cover the subject on hand may be mentioned the extreme yet more appropriate and descriptive term that the French have added, namely, *diabète azoturique.*

In so far as the strict azoturic conditions are concerned, and on the basis of my study of the condition, I would suggest the following classification:

1. Physiologic azoturia.
2. Azoturia simplex.
3. Azoturia gravis.

This eliminates the confusing term of diabetes to which the condition in its medical form may be considered somewhat allied, and gives to us terms applicable to practical medicine.

PHYSIOLOGIC AZOTURIA

For whatever reason an increased oxidation takes place in the tissues of the body, an increased output of the nitrogen-bearing substances in the urine is liable to occur. These include the effects of cold, excessive exercise, sometimes the emotions, physical pain, repeated pregnancies, prolonged digestion of protein foods and the like. While the term "physiologic" can hardly be applied, we can herewith also include those conditions in which an increased output of nitrogen in the urine accompanies certain abnormal states of the body, such as continued fever, some of the acute lesions and functional disturbances of the nervous system, physical pain, and so forth. These conditions are only relative, however, and need not be presented further.

AZOTURIA SIMPLEX

What characterizes this form of the condition is the absence or mildness of the constitutional symptoms, its more acute or limited course, the fact that polyuria is not present or only slightly so, and the output of urea and the phosphate only moderately above normal. It is found in both children and adults, but mostly the latter. Emotions, traumatism, suffering from painful affections and excessive indulgence in food and alcohol are factors in its production. Raymond reports a case lasting thirty-two days with recovery, in which the symptom of polyuria was 2.5 to 5.5 liters, with a daily output of 50 gm. of urea. One of these simple cases may, nevertheless, develop polyphagia, marked azoturia, polyuria and other symptoms, the condition gradually deepening into the grave form. Comby[4] reports such a progressive case with death in three months, but probably this was the grave form at the beginning. In the majority of the instances, however, if the condition has been recognized and treated properly, it subsides after some days or weeks of time, and a complete recovery takes place. Such milder cases are also seen in lesions of the brain and syphilis, and, as Bouchard has pointed out, in the course of diabetes mellitus, when it is an added, independent factor, rather than a related symptom.

It seems reasonable to assume that a long-standing condition of what in its course may be considered as physiologic azoturia may deepen into what is mentioned as azoturia simplex. Such a case may then intensify with the production of the prominent symptoms of the graver form and the issue close with death in the course of time. Like the manifestations of glucose in the urine in diabetes mellitus, the increased amount of nitrogen in azoturia may be more or less transitory at the start, then be more steady and larger in quantity and finally the constitutional symptoms of the condition develop, the case then being of the permanent and grave form. Thus it is that while the condition in its course may remain identical throughout in an individual case, a relationship between the different forms must be kept in mind as a possibility. What may be considered a case of azoturia simplex should make one hesitant in the prognosis, for, while the diagnosis of such a degree of the condition can only be fixed on the severity of the symptoms and the course under treatment, a progression may nevertheless take place. Fortunately, this is not so common as the continuation of a uniform degree.

AZOTURIA GRAVIS

This is the form to which I would particularly draw attention. It is found mostly in male adults of nervous temperament, between the ages of 40 and 45, and those suffering from lesions of the brain and spinal cord, syphilis, painful affections, long-continued use of alcohol and overindulgence in nitrogenous foods. Bouchard was enabled to demonstrate disturbance of the nervous system as the primary cause in three cases; one patient had concussion of the brain, and two cerebral tumors of syphilitic origin.

The primary symptoms are polyuria, polydipsia and especially polyphagia. The polyuria is the consequence of the polydipsia, and if the excess amount of the urea is swept out by fluids the organism defends itself by the polyphagia. There is a noticeable loss of flesh accompanying an exaggerated appetite and thirst. It is the prematurity of the emaciation in its striking course that should direct one to the suspicion of this condition and to the examination of the urine. The absence of sugar should then suggest making an estimation of the quantity of nitrogen or the urea-nitrogen at least. Complications, such as a certain resemblance or analogy with scurvy, various neuralgias, disturbance of the special senses and uremia may arise. Thirst is usually less severe than in diabetes mellitus. An exaggerated and constant loss of nitrogenous material (mostly represented as nitrogen in the urine) is always present. The condition is characterized by the general symptoms of polyuria, polydipsia, polyphagia, abundant sweating, loss of muscular strength, hemorrhages of the retina and vitreous, while in the end the appetite is impaired, emaciation becomes excessive and cachectic edema may make its appearance. Death results through this extreme malnutrition or by way of some complication to which phthisis and gangrene should be added.

---

[4] Comby: Diabète azoturique; mort par complications pulmonaires, France méd., Paris, 1882, ii, 364.

The symptoms usually begin insidiously (but may be abrupt) with a feeling of languor and an unaccountable weariness, especially in the loins and thighs. The tongue is usually pasty and foul, and the edges of it red and irritable. In such an early case the increased craving for food may alternate with complete anorexia. As the case deepens, the gastric disturbance increases and the tendency to anorexia and thirst becomes more prominent. The weariness in the loins and legs is accompanied with actual pain usually on both sides, although it may be only in one loin and strongly simulate renal disturbance. Diarrhea may exist, which contributes to the malnutrition. Sexual impotence and nervous phenomena are usually prominent. Boils may appear, not the large ones of diabetes mellitus, but those of the size of a hempseed with inflamed bases and yellow heads; these come in crops. The skin becomes harsh, dry, and wrinkled from the loss of adipose tissue. It is at this stage that the suspicion of diabetes mellitus becomes keen, and a more thorough examination of the urine is made and the excess of urea with the absence of sugar detected. Toward the end, the respirations become difficult, the pulse weak, and death may occur in the course of the complications.

The disease may take several years to reach its end, and an interesting feature is that near it the azoturia diminishes and may even drop below normal. The principal symptom on which the diagnosis is made is the azoturia, which requires an examination of the urine. The large amount of urea present explains the thirst which is the necessity to dissolve the urea to flush the tissues.

At this point the pathology of the condition may be taken up. There are two main theories. First is a disturbance of the nervous system, and second a disturbance of the liver function. The first cannot be argued away safely, because in most of the cases it is present. This is also suggested in the emotional cases, concussion of the brain, and cerebral tumors of syphilitic origin. Lamy suggests the possibility of a circumscribed area in the floor of the fourth ventricle as a cause.

Just why it is that these cases are encountered in well-to-do men leading sedentary, busy, anxious lives, who for the most part live neither wisely nor well, is not known, but there is no doubt that this strongly suggests some metabolic cause, and the condition continuing, the nervous phenomena ensue, the azoturia not being suspected. This leads us to the second metabolic theory, and some good argument may be presented in favor of it. It is unfortunate that the chemistry of the tissues in the production of urea from its intermediate products is not well understood. Lecorché, with Bouchard, believed that the excess of urea comes from the tissues which are consumed by faulty assimilation and not from the foods. Difficulty arises in regard to the why and wherefore of this nutritional disturbance, and, although the action of the nervous system may be the probable cause, it remains to be shown how it acts. Allbutt suggests that while the pathology of the disorder is by no means clear, it appears to be due to increased metamorphosis of the tissues rather than to protein food. This is suggested in that while a restriction of the protein food effects a certain reducing of the amount of urea, the result is never considerable, and, of couse, a purely carbohydrate diet has very little influence in restricting the amount of urea.

With the knowledge of the activity of the liver in the chemical transformation of certain substances and particularly toward the rapid elimination of materials which cannot be utilized, especially the nitrogen radicles derived from the excess of protein foods, one's interest in the rôle of the liver in this connection as influencing nitrogen metabolism is immediately aroused. It is now generally accepted that the albuminoids with the carbohydrates and fats are utilized in the formation of glucose, and it is a suspicion of mine that in the transformation of the products elaborated in the stomach and intestines into substances which pass into the blood for liver regulation, storage and elaboration, the most plausible theory for the condition exists. Richet illustrates: "With the exception of the action of the fibrin, the coagulability of the blood and the uropoietic function, not much can be said of the action of the liver on nitrogenous substances." We are still arguing the disputed theory of the proteins of the serum being synthetically formed by the intestinal mucous membrane from the nitrogen products derived through digestion, which is a direct contradiction to the existence of a nitrogen function of the liver. One is not inclined to agree with Abderhalden in this theory, because it implies a refutation of the chemical transmutation in the formation of urea and the splitting up of the ammonia contents by the liver to bring this about. It is further confusing when one considers that the alimentary albumins are subjected successively to different proteolytic ferments before they are broken up into amino-acids. Delaunay seems to have shown that the amino-acids are not utilized in the synthetic formation of the albumin of the blood-serum by the intestinal mucosa, but pass directly into the portal vein and are carried into the liver as hexoses. The liver probably then plays a triple rôle in its action on these hexoses. It decomposes the amino-acids not utilized by the organism, either because they are not easily absorbed or because they are formed in excess. The amino-acids are thus transformed into urea and ammonia. The carbon radicles, on the contrary, which present a source of energy, are utilized. Whether or not the liver tissue stores up any quantity of amino-acids for fasting periods, is still somewhat of a question, but there is now a strong reason to believe that it does send quantities of amino-acids into the circulation to be utilized by the tissues, and that in so far as the amino-acids in the blood are concerned, the liver regulates it as it does the carbohydrate radicles.

To bring these few facts together in an etiologic way in connection with the subject, we can all agree that in disease of the liver, amino-acids are frequently removed in the urine; in fact, this is one of the surest signs of hepatic insufficiency. Adding to this the analyses of such matter as I know of pertaining to the subject, I am strongly inclined to believe that the condition is hepatic in origin in which the pancreas also plays an important part, because we know that the pancreas has to do with transformation of the nitrogen bodies as well as the carbohydrates.

The diagnosis is made by the examination of the urine, for which a twenty-four-hour specimen is required. The amount excreted is usually about 5 liters, sometimes running as high as 20 liters. The urine is of a light or dark color, of a very pronounced acidity, and the specific gravity often exceeds 1,040 or even 1,050. A feature of the urine is its promptly acquiring an ammoniacal odor caused by the large amount of nitrogen-bearing substances being broken down by bacteria. The chemical analyses disclose an absence of glucose and albumin, although an albuminuria of a low degree may exist in the beginning.

When the specific gravity is low, between 1.002 and 1.010 for instance, the diagnosis of diabetes insipidus is suggested, while, of course, when glucose is present, the diagnosis of diabetes mellitus is in order. A point to remember is that in nephritic polyuria one always has an albuminuria with casts together with cardiac disturbances, and the manifold manifestations of arteriosclerosis and uremia. Usually in the azoturic conditions the quantity of urine increases during the day, and at intervals of some hours after the meals; the latter depends on the character of foods eaten.

The main feature of the urine is the azoturia present, this meaning an excess of urea, uric acid, and nitrogenous extractive substances. In the course of twenty-four hours the urea output is between 40 and 150 gm. (normal amount, 25 gm., although lately this has been considered too high, and 16 gm. is now considered as the upper amount), the uric acid reaches 9 gm. (normal amount, 0.7 gm.), the nitrogenous extractives of creatinin and uroxanthin reach and exceed 70 gm. The excess also involves the chlorids and phosphates, the first of which may be between 15 and 30 gm. (normal amount, 13 gm.), and the latter represented in phosphoric acid from 5 to 6 gm. (normal amount, 3 gm.). In the absence of facilities to make the nitrogen partition, urea may be taken as the diagnostic index of the condition. Of course, the accurate methods of analyses of Mörner-Sjöqvist and that of Folin are advised, but when these are not practical, the ordinary urinometer multiplying the quantity of nitrogen obtained from 1 c.c. by the number of cubic centimeters of urine voided is sufficient for clinical purposes. The presence of a moderately increased amount of urea suggests the simple form, while the presence of a large amount with the characteristic general symptoms suggests the grave form. The Ehrlich aldehyd reaction, which is uniformly positive, should also be noted. It is advised in all cases of diabetes mellitus, phosphatic diabetes and even diabetes insipidus, that urea estimations be made, because the case may be a combination one, and when present with glucose it is much more serious. At this point it may be mentioned that while mellitic diabetes cases are common, phosphoric diabetes, or better phosphaturia, is less common, and azoturic diabetes, or better the forms as I have classified them, the rarest of all. It is important to keep in mind that azoturia may exist with diabetes mellitus, in which instance the prognosis is much worse than it would be when either condition exists alone.

The treatment suggests that more urea estimations of urine should be made in a general routine way, for by it all cases of the simpler forms would be suspected early enough and successfully treated. The condition established, the treatment is a judicious management to prevent further mischief. An absence from work is essential, and a sojourn in the country may be sufficient for the simpler forms without further treatment. The patient should arise late and go to bed early so as to soothe the nervous system. In order to limit the loss of urea the avoidance of movements and fatigue must be recommended. The bowels should be kept well opened, and a tepid sea-water shower or bath and a good toweling has been recommended by Ralfe. While care must be exercised not to let the temperature be too low, it is important not to let the patients be relaxed by overheated rooms or clothes which are too heavy.

While on the one hand it seems advisable to influence the amount of nitrogen in foods, on the other, it has not been so practical as placing the patient on a general diet. The main point in the dietetic treatment is not so much to control the nitrogenous element as to control all quantities of food so that the tissues are not oversupplied and the patient still is well enough nourished. This plan controls the general symptoms as well as the urinary ones, but is somewhat short in the repair of the loss of tissue, but if the patient recovers sufficiently, it is warranted to increase the quantities of nitrogen as well as the carbohydrates and fats — this means more food.

Some difference of opinion exists as to the value of different drugs, although most authorities agree that valerian answers the best purpose. Bouchard employed it with good results in the form of the extract in gradually increasing doses, beginning with 8 gm. in fractional doses during the day, and increasing rapidly to 20 to 30 gm. in twenty-four hours. Others recommend the use of arsenic, potassium bromid, belladonna and hyoscyamus. It is probable, however, that the best are valerian, opium and arsenic.

The prognosis in the various forms mentioned is according to the degree, the length of time the condition has been standing, and presence of complications. When properly treated all of the cases of the simple form are cured, while in most of those of the grave form the patients are relieved of their symptoms so that they can continue a number of years of life. In the presence of complications, however, but little could be expected. This means an extreme extent of breaking down of tissues and usually marks the threshold of the end.

THE TREATMENT OF PELLAGRA

AN OPTIMISTIC SURVEY OF ITS PRESENT STATUS

GEORGE M. NILES, M.D.
ATLANTA, GA.

It is admitted at the outset of this study that the etiology of pellagra is unknown. The antizeists, or those who do not believe in Lombroso's theory of a toxic cause existing in spoiled corn, corn products, or perhaps carbohydrates, seem to be somewhat in the ascendancy just now, though there are certain historic and sociologic facts that have not been disproved which link together pellagra and maize. The theory that the disease was produced by the ingestion of semidrying edible oils progressed only to the nebulous stage, and then apparently vanished into thin air. Sambon has practically forsaken his hypothesis concerning the *Simulium reptans,* and at present the accusing finger of the Thompson-McFadden Commission for the Study of Pellagra seems to be pointing toward the *Stomorys calcitrans,* or stable-fly.

No constant or distinctive pathologic changes have been noted in this disease, though the complex of symptoms seems to rest on certain trophoneuroses similar to the degenerations incident to senility.

Many earnest research workers are investigating this problem, and its early solution is hoped for. Meanwhile, the pellagrins are clamoring for therapeutic relief; and the wavering theorist, who hesitates to minister to these sufferers because not all these etiologic and pathologic inquiries are clearly answered as yet, as well as the dismal pessimists who can see nothing of light ahead — these should exercise their doubtful talents in other fields, leaving the warfare to the resolute and courageous spirits who are willing to fight, even if much of the battle-field is as yet shrouded in darkness. Malaria was treated with a measure of success before Laveran demonstrated the *Plasmodium malariae,* and bacillary dysentery was fairly well managed before Shiga determined the cause. The treatment herein advanced, embodying suggestions from several observers of recognized standing, and built on my own experience in the care of over six hundred cases, is yielding satisfactory results and rests on the four basic supports of hygiene, diet, drugs and hydrotherapy, buttressed with a hopeful and helpful psychotherapy.

HYGIENE

The hygiene of pellagra is similar to that of other exhausting diseases, with two exceptions. The first is that alcoholic beverages in any amount seem to be highly detrimental. While an occasional alcoholic stimulant may be of questionable aid in conditions of extreme weakness, I would hesitate to give a favorable prognosis to any pellagrin of convivial habits. I make this statement confidently, though it is at variance with the opinion of an estimable medical friend. The second exceptional hygienic precaution is that sunlight, direct or reflected, should be avoided during the spring and summer months; and danger also lies in becoming overheated. The actinic rays have a peculiarly irritating effect on the skin of pellagrins, which is seemingly most marked in early spring. Exposure to these rays or to radiant heat from a stove or furnace will, in a pellagrin, bring out an erythema, or will renew one that has been apparently healed. Pellagra flourishes in hot weather and subsides in cold: consequently the sufferers fare much better if they can keep in a cool environment.

DIET

In the diet, I prohibit corn-bread and corn products, unless I know positively that the corn is fresh and has undergone no "heating." Until the "zeist" theory is thoroughly disproved, we owe our pellagrins this precautionary measure.

As to other dietetic measures, we should remember that in this malady the gastro-intestinal manifestations are the expression not of a disease primarily localized in that tract, but of a centralized irritation, plus the effect of toxins eliminated through the gastro-intestinal mucosa. As demonstrated by me four years ago, the early diarrhea is mainly of central origin, and to some extent compensatory. It therefore does not require a too limited regimen, nor does such seem to aid the disordered bowels. Woody vegetables and those yielding a large amount of residue are mechanically contraindicated at any time diarrhea is present, but care should be taken to replace them with other nourishing food. I have also demonstrated that the flesh proteins are especially well borne. Tender broiled steak, roast beef or mutton may be allowed once or twice daily; or, if the mouth is too sore to allow chewing, beef or white meats, either scraped or ground, may be substituted. Eggs are generally permissible, though it is well to use only the whites if flatulence exists.

Sweet milk is valuable when it agrees with the patient, though it rather often causes flatulence and distress. The practice of advising the daily consumption of immoderate amounts of milk and eggs, without determining the digestive ability of the patient, is reprehensible and unscientific. Fresh or artificially soured buttermilk is nearly always suitable.

When constipation is present, oatmeal, tender vegetable purées, thoroughly baked Irish (not sweet) potatoes, or cereals with little sugar, will aid intestinal peristalsis. During the whole course of pellagra the invalid must be nourished to the limit of assimilation, and it will generally be found that the gastro-intestinal tract in this disease will bear and care for more aliment than when similarly inflamed from other disorders.

DRUGS AND HYDROTHERAPEUTIC MEASURES

Hypodermically, I use the ampules of iron arsenite solution (16 minims) and sodium cacodylate solution (3/4 grain of the salt), on alternate days, injecting them under careful aseptic precautions, and giving one daily for about two weeks. After that I give an ampule every other day, still alternating the ampules. After the acute symptoms seem to be controlled, I continue giving two injections weekly (still alternating the ampules) for several months. Sometimes, when the patient is anemic and quite nervous, I substitute for the two previously-mentioned ampules the ampules of the green citrate of iron (1 c.c.) and glycerophosphate compound (1 c.c.), alternating as before. I never use the large doses of sodium cacodylate.

Internally, I employ a combination of saturated solution of potassium iodid and Fowler's solution, in the proportion of five of the first to three of the second. Beginning with 5 drops in water, three times daily after meals, the dose should be increased one drop each day, until symptoms of arsenical saturation are manifested. This generally appears when 20 or 30 drops are being taken. When there is puffiness about the eyes on arising, I stop the drops for two days, beginning again at the minimum dose of 5 drops, and increasing as before. This procedure I continue until the eruption and sore mouth are abated, and then continue it in 8- or 10-drop doses for several months. Should there arise a gastric or intestinal intolerance, which is occasional complication, it may be necessary to reduce the proportion of Fowler's solution to one or two in eight parts, instead of three.

For the frequent diarrhea I have obtained satisfaction from bismuth betanaphtol and resorcin, with milk of bismuth as a vehicle. This failing, I give 15 grains of tannigen after each loose action, or, as a last resort, powdered opium. I have also found useful a colonic injection on alternate days of plain coal-oil (kerosene oil). One pint should be injected, with the patient in the knee-chest position, and allowed to remain from a quarter to three-quarters of an hour. Two to four injections are usually sufficient.

For the infrequent constipation, either castor oil, liquid petrolatum, phenolphthalein or enemas will serve, drastic cathartics being inadmissible.

For the sore mouth, a solution of thymol, 1 grain to the ounce of water, a little alcohol being used as a solvent, will generally prove sufficient; or a 25 per cent. solution of boroglycerin. For the stomatitis and glossitis, a daily application of a silver nitrate solution (20 grains to the ounce of water) is in most instances efficacious.

I have ceased stomach lavage, except in rare instances, when a great excess of sticky mucus constantly arises.

The simple erythematous rashes or even the sloughing conditions in the hands and feet may be benefited or cured by the bland ointments, such as zinc oxid, or a 5 per cent. boric acid. Raw or weeping surfaces are soothed by a lotion of calamine and zinc oxid in lime-water, to which may be added a little rose-water or other pleasant adjuvant.

For the intense burning in the hands and feet, so often and bitterly complained of, either ice-cold compresses of a mild solution of mercuric chlorid, phenol (carbolic acid), 60 grains to the pint, applied at frequent intervals to the unbroken skin, or baths of hot mustard water are indicated. Two- or 3-grain doses of acetanilid, or 5-grain doses of acetylsalicylic acid, when the heart action is fairly good, will greatly relieve the neuralgic pains, while brisk rubbing with petrolatum to which has been added capsicum or menthol is advisable for the pseudorheumatic pains in many joints and muscles.

After the erythema has subsided, leaving a rough and harsh surface, alcohol rubs at frequent intervals will facilitate the disappearance of this horny layer. I do not favor salvarsan.

Transfusion of blood from either healthy donors or healed pellagrins is still an available method in selected cases, but its difficult technic and other obstacles will probably prevent its general employment. Drainage of the gall-bladder, appendicostomy and other surgical measures have their advocates, but are seldom, if ever, really expedient.

Special treatment of the purely mental symptoms cannot be covered here. Should such symptoms predominate, deepening into melancholia, or lapsing into dementia, the patients should be placed in an institution for the mentally sick, as it is unwise, because of their varying or suicidal moods, to attempt their care at home.

Hydrotherapy has in many instances proved so beneficial in pellagra that some form of it, such as hot or cold baths, simple or medicated douching, packs, moist or dry rubs, accompanied by special massage, may be employed in nearly every case. Increased oxidation of the tissues, more rapid elimination, greater metabolic activity, sharpened appetite, improved digestion and assimilation, and a noticeable tonic effect on the whole living organism follow their use.

PSYCHOTHERAPY

Just now, when a wide-spread pellagraphobia prevails, when the unhappy victim finds most hospitals, hotels and boarding-houses closed to him, and many nurses unwilling to attend him, can we wonder that the knowledge of its presence carries distress of mind? Much of the fear of this disease is due to unwise words of physicians, perhaps lightly spoken, but deeply impressive and harmful to the already perturbed pellagrin. It is wrong for the physician, in any way, to add to the anxiety of the patient, and every legitimate effort should be used to encourage and cheer him. He should be assured that he does not endanger his family and friends, that many cases are permanently cured, and that energy and perseverance on his part will greatly brighten his prospects. Though pellagra is always a grave malady, an unfavorable prognosis, except in extreme cases, should not be hastily given.

"Apparently some regenerations may take place in diseased organs of highly organized type, if the patient's condition is kept up to the highest point of nutritive efficiency" (Walsh). I have in mind a young woman who has been well for over two years, but whose condition at one time seemed to be hopeless; and this taught me a salutary lesson. Certain compensatory influences may be begun and continued by drugs and other material aids, but more often they are hastened by conserving the bodily and mental tone during the prolonged period that Nature demands in which to educate new centers and adapt herself to the loss of others.

I have in several instances seen pronounced psychoneuroses seemingly arise from discouragement, from the sluggish conditions which develop in the bodies as a result of lack of hope, and from the refusal to take air and exercise which accompanies despair. In pellagra, as in many other complicated diseases, many intercurrent ills arise at frequent intervals. Many of these can be promptly alleviated, and a much more sanguine frame of mind may be induced even if the main lesion is untouched. As one writer has well said, "Though nothing can be done for the disease, much can be done for the patient." In such conditions the Eddyites, the mental healers, and the quacks get their occasional spectacular results.

The belief is reasonable that by suitable suggestions we can delay, if not arrest, nerve degeneration, for a buoyant body and hopeful mind present a firmer bulwark against cellular destruction. Therefore, while recognizing the easily managed intercurrent ills and promoting comfort, the physician and those around the patient should try to inspire courage and optimism in him, so that the higher psychic centers may exert their untrammeled influence over the lower centers.

PROGNOSIS

My experience in the treatment of over six hundred cases has taught me that there are four classes in which the prognosis should be extremely guarded: persons over 50 years of age; alcoholics; patients with marked mental symptoms, evidencing greatly damaged nerve centers, and those intellectual weaklings who capriciously veer from one plan of treatment to another.

On the other hand, if the patient is under 50, and has sufficient intelligence and perseverance to adhere to a fixed line of treatment, and will faithfully cooperate with the physician, a permanent cure may be expected in the majority of cases.

920 Candler Building.

Athletics and Cardiac Hypertrophy.—From the data presented it is clear, I think, that severe athletic contests cause marked cardiac hypertrophy in individuals who are strong enough to take part in them. The cardiac hypertrophy gives greater capacity to stand prolonged severe muscular exertion, but is usually associated with some signs of functional disturbances. About the ultimate result in the life of the individual of an athletic heart acquired in youth we know little. For ordinary vocations and avocations an overlarge heart can be of little use. Unless it is kept exercised it will assuredly undergo detrimental retrograde metamorphosis. Furthermore, most pathologists believe that the musculature of a hypertrophied heart is always somewhat diseased and less resistant than that of the normal heart. The degree of myocarditis varies in different individuals.—C. R. Bardeen, M.D., *Wisconsin Med. Jour.*

THE PLAGUE OUTBREAK IN PORTO RICO

S. B. GRUBBS, A.B., M.D.
Surgeon, United States Public Health Service
PROVIDENCE, R. I.

On June 15, 1912, bubonic plague was discovered in Puerta de Tierra, a squalid district outside the old walls of San Juan, Porto Rico. The positive diagnosis was made three days after the first cases were found and so reported to the acting governor by the assistant director of health and the representative of the United States Public Health Service. The governor promptly proclaimed the existence of plague, thus making a record of promptness and honesty.

As was natural, a panic ensued, and the roads leading from San Juan were filled with all manner of vehicles rushing away, many not knowing where. All supposed that a quarantine would be imposed and that no one would be allowed to leave the city, which accounts for much of the rush to be away. Indeed, many in high office strongly urged military cordons, and burning of the districts in which cases occurred, radical measures both useless and severe, which the calmer minds successfully opposed. While the panic was expending itself, those who remained at home, having been instructed to clean up, began throwing their rubbish into the streets, revealing enormous stores of hidden junk and trash. No one imagined that behind those nicely painted walls were such quantities of waste material. The streets were almost impassable within a few hours, although every wagon and cart that could be hired was at work, and every motor-truck was working night and day. This continued for nearly a week, while on the open lots several bonfires, covering a quarter of an acre each, burned day and night. Sixty large motor-trucks of this stuff in one night were taken from old San Juan, which has about 15,000 inhabitants. Seven truck-loads of rubbish were taken from one house, and so on, until one wondered where it all came from and if it would ever end; but both the fright and the fires did finally diminish, so that at the end of a week people were coming sheepishly back, and the expert sent by the United States Public Health Service was quietly at work on the eradication and prevention of spread of the disease, while the Department of Sanitation of the island was caring for the sick.

Bubonic plague is a disease carried by rats and but rarely transmitted by human beings, so the work of eradication was done by killing rats, improving buildings so that they would be poor rat harbors, and by preventing the rats from traveling to other places. The quarantining of persons, the restriction of travel and commerce, spectacular but ineffective methods against this disease, were not used. The business-like and scientific methods employed were productive of a result both brilliant and gratifying, for in ninety-two days after the first case was discovered the disease was over, and although rat-proofing, and the catching and examination of rats still goes on, there is no plague in San Juan, either in human beings or in rats. In all, there were fifty-six cases with thirty-six deaths from this disease in Porto Rico.

Where did the plague come from and how did it reach the island of Porto Rico? While busy with suppressive measures and in preventing the disease from going to other points of the island and to the United States, this was what the quarantine authorities were constantly asking themselves. There is and has been for several years bubonic plague in Venezuela, and the people naturally considered this the source. The United States Public Health Service officers, although admitting that no quarantine restrictions that do not absolutely stop commerce can give absolute protection, did not believe that Venezuela was to blame. They knew that the Public Health Service keeps an officer in Venezuela, who personally watches the ships that are to sail for Porto Rico, who goes on each one from port to port and fumigates each vessel before she sails. They knew that these vessels were constantly watched at San Juan, so that while commerce moved with but little hindrance, the chances of any Venezuelan rat landing in Porto Rico was exceedingly small. It was consequently believed that plague infected rats had come from some place where the disease was not recognized or where its existence was denied.

Many ports were suspected only to be vindicated, until Dr. Juan Guiteras, formerly an officer of the United States Public Health Service, and now director of health of Cuba, suggested the Canary Islands as a possible source, saying that five or six years ago there was an epidemic in Santa Cruz de Teneriffe, which some said was plague. As it is well known that epidemics of human plague will subside and become endemic, existing in rats for years, unless intelligently and persistently combated, the time elapsed was no argument against this theory, so an investigation was made with the result that it may now be said that in all probability plague came to Porto Rico from the Canary Islands.

Not only have many disinterested persons testified to the existence of plague in Santa Cruz, but no less a person than Dr. L. Comenge, royal delegate to investigate the epidemic in that city in 1906-1907, made a report to the Spanish government in which he states that the disease was plague and that it existed in rats and human beings, sixty-nine persons being stricken. He also reports that while knowing it to be plague he suppressed this knowledge, apparently believing that the tranquillity and commerce of the Canary Islands was more important than the health of the world. In this policy of suppression the authorities to whom the report was submitted must have agreed, for the report was not made public or the presence of the disease announced.

There is, however, other interesting evidence. About two weeks after the discovery of plague in San Juan, a case was discovered in Havana, Cuba, then another and another, in all three and then no more, bespeaking both a light infection and brilliant work. The Atlantic and Gulf coast ports began to put themselves in order and to catch and examine rats, with the result that one infected rat was found in New Orleans, so that the warning from Porto Rico saved that port and probably many more. Then there was some plague among the rats in Liverpool, and that was stopped in time. There is evidently some connection between these events, for the steamers of one of the Spanish lines after making many Spanish ports, one of the last being Santa Cruz de Teneriffe, where they take onions and potatoes in crates and baskets, go direct to San Juan (plague June 15, 1912), next they go to Havana, Cuba (plague July 4, 1912), next to New Orleans (plague-rat found July 27, 1912), and then some of these steamers go to Liverpool (plague-rats found August 1 and 30, 1912). This evidence is circumstantial, but with the knowledge that plague existed in Santa Cruz de Teneriffe in 1906 and 1907, the conclusion is evident that plague came to San Juan, Porto Rico, carried by a rat from Santa Cruz, on a Spanish steamer, probably in a crate of onions or potatoes, and that the same line of steamers that brought the disease to Porto Rico carried it on to Havana and probably to New Orleans.

Quarantine is at best a compromise that tries to give the greatest amount of protection with the least amount of obstruction. It must rely on information as to the health of other places, and when such information is false, a non-prohibitory quarantine is powerless.

Honesty and fair dealing in questions of epidemic diseases is necessary if international sanitation is to advance, and if such histories as those of plague in Porto Rico and Cuba are not to be repeated.

IS THERE A TOXEMIA REFERABLE TO THE EATING OF CHESTNUTS?

THEODORE C. MERRILL, M.D.
WASHINGTON, D. C.

This paper is offered in order to suggest the possibility implied in the title, and to elicit any comment which its publication may induce. In fact, such comment is invited. Search in the literature has thus far been barren of reference, yet it may be that such reference has been overlooked, or that some physicians have knowledge of conditions occurring as in the present account. During the months of October and November, 1913, numerous newspaper reports called attention to cases of sickness and death alleged to be due to the eating of chestnuts obtained from blighted trees. These cases were reported from Hartford, Conn., and vicinity, from a town in New Jersey, from several places in Massachusetts, and from a point in New Hampshire. I undertook investigation with a view to ascertaining the facts giving rise to the reports. The results of the study are here set forth.

PRELIMINARY CONSIDERATIONS

1. *In Healthy Chestnut Trees.*—The fruit (so-called nut) of the healthy tree is not supposed to be toxic. Germination, however, is remarkable for chemical (enzymic) activity, and it should not be forgotten that at this period liberation of toxic substances may not be impossible. Analogy is seen in the instance of growing sorghum, hydrocyanic acid compounds appearing in the immature plant. Hydrocyanic acid compounds, nitrobenzene or toxalbumins may not reasonably be imagined as being possibly present in germinating chestnuts; whether they are in fact present or absent has not been determined.

A period of unusually warm, dry weather in the fall, followed, at the time of chestnut maturity, by copious rains, tends to induce germination in the nuts while still on the trees and after they fall to the ground. Such germinating chestnuts, though healthy, cannot

be considered as decisively free from substances toxic, as above indicated.

2. *In Unhealthy Chestnut Trees.*—The chestnut bark disease, or so-called "blight," whose spread is now extensive and destructive in the New England States, New York, Pennsylvania, New Jersey and other states comprising the eastern portion of the chestnut range, is due to infection of the bark by a fungus (an ascomycete) called *Endothia parasitica,* or, formerly, *Diaporthe parasitica.*

The fungus infects by lodgment of spores in a wound or wounds occurring in the bark, the mycelium spreading circumferentially so as finally to girdle the infected twig, branch or trunk. The mycelial development interferes with nutrition in the part attacked, so that, when girdling is complete, or nearly so, structures distal to the lesion die.

While infection of the nut, directly by implantation of the fungus, has been noticed, such infection appears to be rare; moreover, nuts obviously infected are not likely to be eaten. Influences affecting the edible portion of the nut should occur by alteration of nutrition, as induced by the mycelial growth in the bark. Circulating sap, perverted quantitatively, qualitatively or both, may produce nuts immature, undersized or conceivably containing toxic substances absent in the healthy chestnut.

REPORT OF INVESTIGATION

The accompanying tabulation shows an analysis of characteristics ascertained to be dependable. No assertion is made that they are to be ascribed positively to the eating of chestnuts as cause. The *post hoc,* though present, is not here intended necessarily to mean *propter hoc.* Since the chestnut season is now over for this year, it may well be that reservation of decision will be required for one or more further seasons. Food-poisoning, aside from chestnuts, is excluded in the present series.

The characteristics, as grouped, follow, with some slight, unavoidable overlapping, a classification based obviously on the physical (splanchnic, somatic) systems affected in the respective cases.

In connection with this tabulation there are certain conditions which tend to contravene the idea here related to the etiology. Thus, the circumstances in Case 19 are complicated by the presence of an undoubted case of poliomyelitis convalescent in the vicinity; again, Case 7 is not accompanied by proof whether or not chestnuts were eaten. The eruption in Case 21 was mostly papular, slightly papulovesicular, and general, being especially conspicuous about the mouth, anus and prepuce. In connection with the subject of eruption as related to chestnut-eating, the tabulation indicates noticeable absence of eruption in cases undoubtedly associable with ingestion of chestnuts—a condition at variance with an elicited *viva voce* tradition to the effect that skin eruption and sore mouth are sequelae not uncommonly incidental to the eating of chestnuts.

The topic "great prostration" implies in every instance an effect disproportionate to any apparent cause.

Chemical and biologic examination of chestnuts is now going forward. It is hoped that the result of the study may be given in a future paper.

Cordial acknowledgment is made of suggestions and criticism kindly granted by Drs. W. T. Councilman, Reid Hunt and C. J. White, of Harvard University, Dr. Morris Longstreth of Cambridge, Dr. C. K. Mills of the University of Pennsylvania, Dr. Steiner of Hartford Hospital, Dr. C. C. Beach and other physicians who furnished valuable assistance in promoting this inquiry.

SYPHILIS IN THE MEDICAL DISPENSARY*

E. B. KRUMBHAAR, M.D.
AND
C. M. MONTGOMERY, M.D.
PHILADELPHIA

The general medical dispensary offers one of the avenues of attack on the important problem of the control of syphilis, which to-day lags sadly behind our knowledge of the pathology and treatment of the disease. It is important to recognize, first, the frequent occurrence of this disease in the medical dispensary. Out of a thousand consecutive new cases in the medical outpatient department of the Pennsylvania Hospital, thirty-four were diagnosed as luetic, of which thirty gave positive Wassermann reactions. The last-named figure is 3 per cent. of all the dispensary cases, probably considerably below half the actual proportion of patients attending the dispensary who have contracted syphilis. Even in those patients in whom the symptoms could not be attributed with absolute certainty to syphilis, the presence of the Wassermann reaction indicated the employment of specific treatment. The second point to be emphasized is that a large proportion of the patients in medical dispensaries present themselves when cure or distinct improvement is still within reach. While most of the cases have passed the primary and secondary stages, the patients often come before any definite demonstrable lesions have appeared, or while such lesions are still capable, if not of a cure, of marked improvement, or of having the progress of the disease arrested.

The data forming the basis of this paper were gleaned from the records of 108 cases tested for the Wassermann reaction in the Pennsylvania Hospital Medical Dispensary. These cases may be briefly classified as in Table 1.

TABLE 1.—CLASSIFICATION OF 108 CASES

	No. of Cases	Male	Female	Average Age, Years
Wassermann positive, 48 cases:				
Congenital	5	3	2	9
Secondary	3	3	0	28
Tertiary	40	33	7	38 2/5
Wassermann doubtful, 7 cases:				
Luetic	4	3	1	37 ½
Non-luetic	3	3	0	33
Wassermann negative, 53 cases:				
Luetic	1	1	0	47
Non-luetic	52	41	11	38 3/10

It is our desire, within the brief limits of this paper, to utilize the facts gained from a study of these cases to focus attention on a few of the many important aspects of the subject of syphilis in the general medical dispensary. The first point to be emphasized is the difficulty of recognizing many of these cases on account of the obscure guise in which they present themselves. Making a diagnosis in many of the cases is seriously hampered, because three of the main lines of investigation yield no definite information. The past history may be negative, the symptoms may be vague and indefinite in the extreme or even altogether absent, and abnormal physical findings may be slight or wholly lacking.

---

* From the Out-Patient Department of the Pennsylvania Hospital.

The first point is well illustrated by Table 2, in which the past history refers to venereal sores; secondaries or miscarriages, or to more than one of these.

TABLE 2.—SYPHILITIC HISTORY

	No History	History Present
Positive Wassermann, 48 cases	20	28
Doubtful Wassermann, 7 cases	4	3
Negative Wassermann, 53 cases	33	20

The unreliability of such negative histories in these particulars has struck the attention of all who have interested themselves in this subject, and is encountered in a large proportion even of intelligent and private patients. Over 35 per cent. of our positive Wassermann cases presented negative histories, and among those with a history of venereal sore the description was often too vague to determine its character. A history of venereal sore was obtained in eighteen of the positive Wassermann cases, in which all the patients were males but one, a history of secondaries in only three, all the patients being males, and a history of miscarriages in six, occurring in four of the seven non-congenital cases (female patients), and in one congenital and one non-congenital case (male patients). These negative responses were probably not due in most cases to any desire to evade the truth, but occurred rather because the early manifestations were not recognized by the patients or were so slight that they were disregarded. It is doubtful if more careful questioning would have materially altered these figures. The difficulties in diagnosis are also demonstrated by the large proportion of positive histories among the supposedly non-luetic cases.

The second point illustrating the difficulties in the diagnosis of syphilis in the medical dispensary is the symptomatology. While some symptoms are relatively suggestive, many of them are absolutely indefinite as to either the presence or absence of the disease. To consider but a single symptom, we find pain frequently in both the positively reacting and the negatively reacting cases, though oftener in the luetic, in which it occurred in 75 per cent. of the cases in contrast to 62.3 per cent. of the non-specific cases.

TABLE 3.—PAIN

	Wassermann	
	Positive	Negative
Pain absent	12	20
Pain present	36	33
Head	11	5
Chest	10	9
Abdomen	9	5
Back	6	7
Limbs	11	9
General	7	3

From Table 3 it will be seen that pain occurred either as general pain or pain localized in one or more portions of the body; but one looks in vain in most cases for any distinguishing features about these pains. Other symptoms occurred likewise in great numbers and variety, and beyond mere mention of their frequent vagueness and indefiniteness cannot be discussed here. Our point is further demonstrated by the tentative diagnoses made prior to the examination of the blood. Thus of nine cases diagnosed as muscular rheumatism, three gave a positive Wassermann and were considered to be specific; out of fourteen classified as gastro-intestinal there were six luetic, while three out of eleven cardiovascular cases, two out of seven respiratory, two out of fifteen nervous cases, and three out of eighteen miscellaneous cases proved eventually to be syphilitic. It is also well known, as demonstrated by one of our cases, that a positive Wassermann may exist in the absence of all symptoms.

The third great difficulty that presents itself in the diagnosis of these cases is the frequent absence of any clearly demonstrable local lesion. Thus out of the forty-eight positive Wassermann cases, nineteen (39.6 per cent.) gave no abnormal physical findings, and fourteen more revealed only adenopathy. In the remaining fifteen cases there were several with conditions such as cardiovascular and nervous that could be considered as no more than suggestive.

Of course, when the history and symptoms and physical findings are considered together, the available information becomes much more valuable; but even when we have obtained everything possible from all of these sources, there are still many uncertain cases that will remain obscure. This assertion is demonstrated by many of the diagnoses in these cases made prior to the employment of the Wassermann test.

The great value of the Wassermann test in many of these cases cannot be overestimated. Thus among the forty-eight positive cases, nineteen were tentatively diagnosed under other headings at the first visit, and in a large proportion of the remainder a good deal of uncertainty existed as to the specific nature of the cases. The great need for this test was further shown by the large number of suspects who reacted negatively, in the majority of which there was no reason to question the reliability of the negative findings.

The other special matter which we wish to mention briefly is the subject of treatment and results. How unsatisfactory they are in medical dispensary work is well known; but the seriousness of the situation has failed to stimulate effort sufficiently in behalf of practical results. Imperfect treatment is a serious economic blunder on the part of the dispensary, while to the patient it may result in the loss of life. Our results in forty-eight positive Wassermann cases are briefly summarized in Table 4.

TABLE 4.—NUMBER OF VISITS AND RESULTS

No. of Visits	No. of Patients	Improved
1	24	..
From 2 to 5	13	7
From 6 to 10*	7	6
From 11 to 31†	4	4

* Of these cases 1 out of 4 later yielded a negative Wassermann.
† Of these cases 3 out of 3 later yielded a negative Wassermann.

Three of the one-visit cases were seen only a few weeks before the writing of this paper. None of the patients have continued treatment over seven months, though a few are still under observation. The figures speak so plainly for themselves that comment seems superfluous. In this connection, Fournier's statement is instructive, that 78 per cent. of cases of tertiary syphilis give a history of insufficient or improper treatment. He also states that over 8 per cent. give absolutely no history, and over 20 per cent. more have received treatment for less than three months. The best way of treating these patients cannot be entered into here, beyond emphasizing the great value of salvarsan. We do wish, however, to insist most forcibly on establishing some method by which the treatment decided on shall be carried out to completion. Sufficient time should be taken to impress the patient with the importance of full treatment, and in explaining its details, and that essential ally, the social service department, should be called on to follow up all negligent patients.

SUMMARY

Syphilis forms a considerable proportion of all cases among persons applying to the general medical dispensary — at least 3 per cent., according to our figures. It usually presents itself at a time when cure or marked improvement, or much in the way of prevention, are still available. The manifestations of the disease in the medical dispensary are often very obscure and misleading, and the cases form a group quite distinct from the type ordinarily encountered in the genito-urinary dispensaries, or in special dispensaries like the surgical or nervous dispensaries, in which the patients usually present distinct symptom-complexes or localizing phenomena. Students should be given more special instruction in these atypical types of the disease, and should be impressed with the need of being constantly on the lookout for cases of syphilis in their medical work. Dispensaries should have as nearly as possible a definite routine method of treating the disease, with the use of salvarsan occupying a prominent place, and every available means, including the cooperation of the social service department, should be utilized to the full in endeavoring to secure the complete carrying out of treatment.

Chestnut Hill—905 Pine Street.

THE CALL OF THE CHILD

FRANCES BRADLEY, M.D.,
ATLANTA, GA.

The federal Children's Bureau is more than justifying itself. At the recent Conservation Exposition in Knoxville, Tenn., the bureau installed as a part of the child-welfare exhibit, a children's health conference to try out a plan of raising the standard of children without resorting to commercial or spectacular methods. The government wanted to know if its future citizens were being given a fair chance, for no phase of conservation can be of more vital or far-reaching importance than that of securing the health and efficiency of the coming generation.

There was also a deep-rooted feeling that all mothers want fine babies, and that their failures are due more to ignorance than to indifference; that they need help rather than prodding, encouragement rather than criticism. So the conference invited all parents to bring their children—not prize babies or sick babies, for neither prizes nor prescriptions were given, but average children—and the average mother was helped by the attending physician to see her child as a future citizen, entitled to the best this country can do for him.

No scoring was done, no comparison or competition was exploited; but the results justified the premise that the natural incentive of parenthood is a safer and more wholesome stimulus than cash prizes or notoriety. Children were brought from all the adjoining towns for examination. It was a revelation to see men as interested as their wives in what would be generally considered woman's work. Business men, club men, university men, farmers, stock-growers, all wanted to know where they stood as fathers.

But one family at a time was admitted to the conference room, where each child was carefully weighed, measured and examined by the physician and parents. The latter were shown point by point where they were succeeding and where failing. Together they went into the child's present, its past, even, if necessary, into prenatal conditions; the sanitation of the home, the hygiene of the family, often its economic condition in its bearing on the nutrition of the child. All legitimate means were used to press home the responsibility of parent to child, and to help them associate cause and effect.

The conference opened its doors to all classes and conditions, and to all ages under 15.

An old countryman covered with whiskers and confusion seemed greatly interested in the conference. Finally, screwing up his courage, he asked the physician in charge why one child should be "little and puny" when others were "big and strong." After a little conversation he declared he was going back to the mountains and get his boy, and he did. A few days later he appeared at the conference room with a big-eyed, wondering wife, six great gawky girls, and a little wizened specimen of a boy fairly wiggling with hookworm.

A university man and his wife brought to the conference a splendid boy of 22 months, so well developed that they had entirely overlooked the faulty articulation of a foot due probably to their overzealous pride in his precocious stunts.

A prominent and wealthy couple brought to the conference an only daughter, so jealously guarded and exclusively trained that they did not even know the child was retarded mentally.

A solicitous and intelligent mother was amazed to have pointed out to her a marked deflection of spine in her supposedly normal child.

A countryman, on being congratulated on the advantages of the country and on the freedom of his family from enlarged lymph-nodes, the commonest defect in that section, replied that he had tried to raise his children "simple and hearty," and he "sho' believed in fresh air." "Why," he added, "yo' could fling a dog through my cabin, jes anywhars." His wife removed the snuff-stick from her mouth long enough to confide, "We comes from Greene County where people leads clean lives and we don't have them things" [enlarged lymph-nodes].

One little youngster brought himself to the conference, for his parents had died in the country, and he had come to town to go to school, but was greatly disappointed because his eyes were bad and he could not study. He was sent to a specialist, who found the sight of one eye entirely gone and the other seriously affected.

These are only samples of the people reached by the conference. The children are no more perfect than their parents, and none but the medical profession can make them so. It is for the American Medical Association to say if it is prepared to meet this call of the child. It must be admitted that physicians do not always measure up to their opportunities. One doctor, for instance, left the toilet of a new-born baby to an old negro granny, who bound the top of a sardine box over the cord to prevent bulging. The baby has doubtless died since of the infection which followed.

A prosperous young mother brought her little starving baby to the conference. "Indeed," she protested, "I have the best children's specialist in B., but you know he is always so rushed he does not have time to tell me all the things I need to know."

It was soon discovered that faulty nutrition was at the bottom of most of the ills of the conference children, and an expert was secured to give practical demonstrations on the care and preparation of milk, the feeding of infants, of schoolchildren, and the wholesome preparation of foods common to that locality. The fact was also disclosed that the bottle-fed baby is a product of the city. Of nearly 900 such children, 545 were raised in small towns of 3,000 and under. Of strictly country-bred children, exactly two were weaned at birth, one because of the death of its mother and the other on account of a "bealing breast."

The average length of breast-feeding was from eighteen to twenty months, though especially unfortunate little victims were kept at the breast for three, four and even six years. This does not by any means imply strict breast-feeding, for the rural child is almost invariably fed, in addition to the breast, a taste of everything its mother eats—"to keep it from having colic." A young mother smiled scornfully when remonstrated with for feeding her baby green grapes—"La!" she said, "he don't think no more o' eatin' them grapes 'n you do o' spittin'."

The proportion of defects varied slightly from those found by medical inspectors of schools, as the children ranged from 3 weeks to 15 years; 541, or 66.6 per cent., being under school age; and enlarged lymph-nodes were proportionately in excess of defective teeth. The East Tennessee child represented a type taller than Holt's standard, 612, or 71.3 per cent., being above Holt's normal, as against 154 below, and 90 corresponding to his standard.

In weight they are nearer normal, 422, or 49 per cent., being below Holt's standard, while 337, or 39 per cent., are above size, and 97, or 11 per cent., normal.

The conference seemed to establish several facts which have been agitating the public mind for a few years past.

1. The medical profession is alive and quite able to care for the children of the country without resorting to hysterical or spectacular methods.
2. It does not need the financial backing of advertising concerns to point the way to its duty. This work may be kept free of commercial entanglement and on the usual high plane of professional activities.
3. The medical profession stands ready to give of its knowledge and efforts to the uplift of mankind, and the little child shall not call in vain.
4. It is to be hoped that the work of raising the standard of our public health may remain where it belongs, in the hands of the government and of the medical profession, and that together they may work out the solution of this most vital phase of conservation.

706 Empire Life Building.

PRECIPITATION TESTS IN SYPHILIS *

PETER K. OLITSKY, M.D.
AND
MIRIAM P. OLMSTEAD, M.A.
NEW YORK

Wassermann, Neisser and Bruck applied Bordet-Gengou's phenomenon of complement fixation to syphilis in 1906. Since then, their principles have undergone many refinements until to-day the method of complement fixation stands out as a test *par excellence* for syphilis. The recognition of natural antisheep red cell amboceptor, the provisions against non-specific complement deviation, the use of inactive serum, the refinement of antigen, the cognizance of anticomplementary effects—all have determined the specificity of the Wassermann reaction.

Owing to the difficulties encountered in a reliable performance of the reaction, methods have been devised for the serodiagnosis of syphilis, having for their main objects simplicity and rapidity. These methods are based on precipitation in luetic serums by various reagents.

R. Kraus,[1] in 1897, discovered the precipitating action of immune serums by bacterial suspensions; but, as the *Treponema pallidum* is so difficult of cultivation, no similar method was used in syphilis to detect antibody. Fornet and Schereschewsky[2] modified this principle by adding the serums of tabetics (luetic) to those of earlier syphilis and obtained precipitations. They found the reaction specific and explained it by declaring that "antigen" existed in early syphilis serum and "antibody" in later. Several factors are concerned here that affect the specificity of this action which we shall show later.

Elias, Neubauer, Porges and Soloman[3] were the first to use a hydrophilic colloid. They employed a 1 per cent. solution of sodium glycocholate and obtained precipitation with syphilitic serums. These authors, however, have failed to demonstrate an absolute specificity in their reaction. Wieder and L'Engle[4] have used sodium taurocholate, taurin solution and distilled water, but while precipitation occurred there was a complete lack of specificity. Klausner[5] obtained a precipitum when fresh syphilitic serum was added to distilled water and allowed to incubate for several hours. Our experiences taught us that some non-luetic serums would give positive while some luetic serums would give negative results. Also, we confirmed Hayn's observation that inactivation as well as aging abolished the effect. Sachs[6] found that the addition of from 1:1,000 to 1:500 normal hydrochloric acid restores this property, but he, likewise, could not determine the specificity of the Klausner reaction. The effect of addition of the dilute hydrochloric acid is of interest in the Wassermann reaction, in which similar results may be had, and is probably due to the acid disturbing the hydroxyl concentration which occurs in inactive serums. Cuorin, used by Teruuchi and Toyada,[7] and lecithin by Georg Meier[8] gave precipitation when added to syphilitic serums, but Meier showed that these precipitinogens had a high degree of non-specificity (50 per cent. of non-luetic serums gave precipitations).

Herman and Perutz[9] modified Elias, Neubauer, Porges and Soloman's reaction and asserted that a precipitation by their method meant syphilis. Remarkable attestations to this specificity have been appearing from then to date.

In 241 cases of syphilis, Thomsen and Boas[10] found the Wassermann reaction to be positive in 86 per cent., while the Herman-Perutz reaction was positive in 48.4 per cent. In 182 non-luetic cases the Wassermann was negative in all, the Herman-Perutz positive in three.

[10] Thomsen and Boas: *Ztschr. f. Immunitätsforsch. u. exper. Therap.*, Orig., 1913, xvi, No. 4.

One case was that of a third stage pulmonary tuberculosis, another of venereal ulcer without spirochetes and the third a case of osteomyelitis and sepsis with subsequent death, necropsy showing no syphilis. In 106 serums Jensen and Freilberg[11] found sixty-three nonluetic, with the Herman-Perutz reaction negative in all, and forty-three luetic with the Herman-Perutz reaction positive in all tested, corresponding to positive Wassermann reactions. Gammeltoft[12] found it a quick and convenient method for diagnosing syphilis. Of 156 control serums (negative) only one (cancer of the liver) gave a positive precipitation, in which case the Wassermann was negative. Ellermann,[13] Lade[14] and Kallós[15] (the observation of the latter two having been made recently) came to the same conclusions, that a precipitation means syphilis whenever it occurs.

We have investigated this question by applying this reaction 259 times to 175 serums. We employed the technic recommended by Herman and Perutz. This is, in short, as follows:

Two solutions are used:

Solution 1 (stock solution diluted 1 : 20 with distilled water before use):

Sodium glycocholate	2.0 gm.
Cholesterol	0.4 gm.
95 per cent. alcohol	100.0 gm.

Solution 2 (freshly prepared before use):
Sodium glycocholate 2 per cent. in distilled water.

The test was performed by adding to 0.4 c.c. of clear inactive serum (56 C. [100.8 F.] for half an hour) in a 7 mm. bore tube, 0.2 c.c. of Solution 1 and 0.2 c.c. of Solution 2. (We controlled the test by adding 0.4 c.c. of distilled water, instead of reagent, to the serums and for each set of tests adding 0.4 c.c. of distilled water to 0.4 c.c. of the reagent.) The tubes were plugged tightly with cotton and set aside at room temperature for twenty hours, when the presence or absence of precipitation was noted.

By this method Herman and Perutz obtained these comparative results: Of 89 non-syphilitic cases, only one reacted feebly (a serum from a tuberculosis patient), of 134 syphilitic serums, 102 were examined. The Wassermann reaction was positive in 72 and negative in 30, and their reaction positive in 76 and negative in 26.

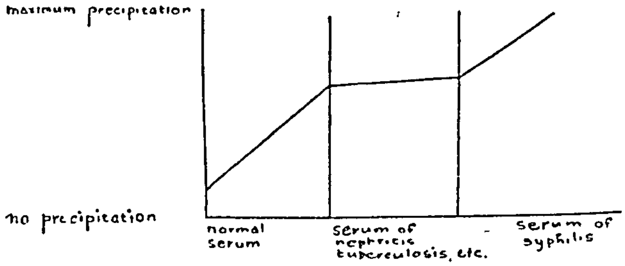
In our series of examinations, the serums were all controlled by first performing the original Wassermann reaction, but using only one-tenth of Wassermann's amounts. Alcoholic extract of normal guinea-pig heart was employed as antigen, and fixation allowed for four hours in the ice-chest. Readings were made just as soon as the controls (containing twice the amount of antigen and serum used in the test) hemolyzed.

In 95 cases of syphilis in different stages we have found 88 giving a positive Wassermann reaction, 7 being negative. Correspondingly, the Herman-Perutz modification, when used, showed 58 positive, 3 doubtful and 34 negative reactions. In 80 non-luetic serums, the Wassermann reaction was negative in all, but the Herman-Perutz test was positive in 16. Of these, 50 per cent. were serums from chronic nephritics. Other positives were found in pulmonary tuberculosis, arteriosclerosis, chronic arthritis, chronic endocarditis, obesity and a normal condition.

Strong[16] likewise found that 10 per cent. of nonspecific serums gave a positive precipitation.

We attempted to obtain more reliable results by trying various modifications in technic. One series of serums was set aside in the ice-chest instead of being kept at room temperature, but no increase in precipitation was noted; two serums of fourteen, however, positive at room temperature, became negative in the ice-chest. Another series was incubated, but the results were far from satisfactory. This temperature offered a good field for the development of bacteria, molds, etc., which interfered with precipitations. Then again, great variations were found between the precipitinogenic Solution 1, when it was diluted by the addition of distilled water drop by drop, or when water was added *en masse*. Analogously to the results in the Wassermann reaction, many more positives were obtained by the former method. The results obtained by using active or inactive serums almost corresponded; but, since some of the positives obtained in active serums were non-specific and since these became negative in inactive serums, it appears best to use inactive serum under all circumstances. In fact, the modification of Herman-Perutz in all details gave the most constant results.

We attempted to substitute the precipitinogen by using an alcoholic extract of normal guinea-pig heart (Wassermann antigen), but there was a uniform precipitation in normal as well as luetic serums. This is due to the presence of alcohol, which has the power to coagulate the albumins present in serum. Others have obtained precipitations by using various fractions of syphilitic liver antigens, yet have not obtained a desideratum for the rapid diagnosis of syphilis.



Curve of precipitation of the Herman-Perutz reaction.

RATIONALE OF PRECIPITATION REACTIONS

We were struck by the constancy with which all serums, luetic or non-luetic, became clouded when these tests were performed. Indeed, only such as gave a distinct flocculation could be regarded as positive. This reaction is a colloidal one. There is a throwing of the sols into gel formation. It is represented by cloudiness of the serum. In fact, particles measuring 100 microns will give rise to haziness, yet the individual masses will be invisible, unless the ultramicroscope is called into play. *The reactions are purely quantitative, not qualitative.*

If, on an ordinate, we were to plot normal serum, serum from nephritis, tuberculosis or conditions in which cholesterol or the albumins have been found to be increased, and then syphilis; and on an abscissa we were to plot the degree of precipitation found by using the Herman-Perutz reaction, we should obtain a curve with its maximum point at syphilis and descending therefrom to normal serum, but never reaching normal serums at zero precipitation.

---

[11] Jensen and Freilberg: Berl. klin. Wchnschr., 1912, No. 23.
[12] Gammeltoft: Deutsch med. Wchnschr., 1912, No. 41.
[13] Ellermann: Deutsch. med. Wchnschr., 1912, No 5.
[14] Lade: Deutsch. med. Wchnschr., 1913, No. 15.
[15] Kallós: Deutsch. med. Wchnschr., 1913, No. 39.
[16] Strong: Jour. Med. Research, 1911, xxv, No. 1.

Other factors appear to interfere with precipitation tests. We have seen alcohol by itself in dilutions from 20 per cent. to 95 per cent. produce a gel formation. Again, serum is contaminated easily and, owing to consequent changes in reaction and surface tensions, spontaneous gel formation may occur. Elias, Neubauer, Porges and Soloman have shown that sodium glycocholate in 1 per cent. dilutions may give very light precipitations in normal serums.

CONCLUSIONS

The Herman-Perutz reaction or precipitation by hydrophilic colloids in general should be regarded as only partially specific. That is, only a heavy precipitation should be considered positive, and then only in a presumptive sense. A diagnosis of syphilis should not be made therefrom, but further investigations of such a serum is in order, especially by means of the Wassermann reaction.

The Wassermann reaction is by far the more reliable of the two.

There is no absolute parallelism between precipitation and complement fixation. The degrees of similarity should not warrant the theory that antigen precipitates antibody, thus binding complement.

Pathological Laboratory, Mt. Sinai Hospital — Research Laboratory, Department of Health.

THE LIBERATION OF FORMALDEHYD FROM HEXAMETHYLENAMIN IN PATHOLOGIC FLUIDS *

PAUL J. HANZLIK, M.D.
CLEVELAND

In a previous publication[1] it was shown that the decomposition of hexamethylenamin in the living normal organism takes place only in acid urine and gastric juice, that it depends on the excess hydrogen ion $[H^+]$ concentration[2] of the fluid, and that in those body fluids which are neutral or truly alkaline (possessing $[H^+]$ concentrations of 7.0 or less), no liberation of formaldehyd from hexamethylenamin takes place. It is conceivable, however, that the reactions of certain pathologic fluids may be truly acid. This might be true of those fluids which exhibit pronounced degrees of stasis, putrefaction or those of clinical "acidoses." With this in view, we have investigated the distribution of hexamethylenamin and free formaldehyd, and the reaction of these fluids, according to the methods described in our previous paper.

Through the courtesy of the various staffs of the Lakeside, City and Charity hospitals of Cleveland, the following pathologic fluids were obtained from patients suffering with different clinical conditions. Usually a dose of 60 grains of hexamethylenamin was given about one hour before the fluid was obtained.

URINES

In twelve urines from persons suffering from acute, chronic and hemorrhagic nephritides, the mean value for the $[H^+]$ concentration was about 6.5; that is, they were truly acid, and formaldehyd was present at all times together with hexamethylenamin. The average time of appearance of hexamethylenamin was seventeen minutes, that is, about the same as normal. In two patients with cystitis, the urines contained hexamethylenamin and free formaldehyd; the $[H^+]$ concentration of several specimens ranged from 6.3 to 6.51; that is, they were truly acid. In another person with cystitis whose urine was alkaline ($[H^+]$ concentration, 7.08), hexamethylenamin was present, but no free formaldehyd. These data indicate that the behavior of hexamethylenamin in urines of various pathologic conditions is about the same as in urines of normal persons, since it is the reaction which is the essential factor in determining the decomposition.

OTHER BODY FLUIDS

Eighteen cerebrospinal fluids obtained from the following conditions; cerebrospinal lues, general paresis, diabetes, alcoholic neuritis, neurasthenia, cerebral arteriosclerosis, leprosy, tabes, epilepsy, pneumococcic meningitis, tetanus and chronic gastritis, showed $[H^+]$ concentrations from 6.98 to 7.3; that is, they were neutral or slightly alkaline, and hexamethylenamin was present in all, but no free formaldehyd. Ten specimens of fresh bile from a patient who was ill with typhoid and had received hexamethylenamin for about four months and was operated on subsequently for cholelithiasis, showed the presence of hexamethylenamin in all of the specimens and typhoid bacilli at the beginning and end of the experiment; no formaldehyd was present in any of the freshly collected specimens and the $[H^+]$ concentration ranged from 6.98 to 7.18; that is, the bile was practically neutral or slightly alkaline. No bactericidal action had been exerted by the presence of the hexamethylenamin. Three specimens of bile from another patient operated on for cholelithiasis gave practically the same results so far as the reaction and formaldehyd liberation are concerned. On standing, some of the specimens became truly acid and showed the presence of free formaldehyd. Two specimens of edema fluid from the extremities showed the presence of hexamethylenamin, but no free formaldehyd, and their $[H^+]$ concentrations were 7.1. In a child with tuberculous pleurisy, hexamethylenamin but no free formaldehyd was found in the chest fluid, and the $[H^+]$ concentration was 7.1. An ascitic fluid showed hexamethylenamin, but no free formaldehyd; the $[H^+]$ concentration was 7.42. The bloods of four diabetic patients showed the presence of hexamethylenamin but no free formaldehyd; their $[H^+]$ concentrations ranged from 7.3 to 7.45; that is, they were slightly alkaline.

The pathologic data indicate that these body fluids contained no free formaldehyd. It would be contended, therefore, that no bactericidal action could have been expected. In our observations, the average and maximum acidity were no higher than in the corresponding normal fluids. With urines, it appears that the average acidity is higher in pathologic than in normal conditions; but the maximum acidity so far recorded is not higher in pathologic cases than the maximum acidity of some normal urines.

CONCLUSIONS

The decomposition of hexamethylenamin in pathologic fluids obeys the same laws as in normal circulat-

ing fluids, and fluids *in vitro* under different chemical conditions. That is, the liberation of free formaldehyd from hexamethylenamin depends on the excess hydrogen ion concentration of the fluid (true acidity).

This investigation is being continued so as to obtain more data, and a more complete report will be published later.

CLAMP RESECTION OF THE URINARY BLADDER

G. KOLISCHER, M.D., CHICAGO
Attending Genito-Urinary Surgeon to the Michael Reese and Maimonides Hospitals

The case which is the subject of this report is interesting from both a diagnostic and a technical point of view.

History.—The patient, a woman aged about 30, complains that during the last eight months she has been compelled to urinate frequently, especially on lying down, that each act of urination is rather painful and also that for the last six weeks the bladder has become the seat of spontaneous pains. The attending physician made a diagnosis of cystitis and tried to improve the condition by flushings of the bladder, which proved futile.

Examination.—I found, on examination, that the urine was cloudy, owing to the presence of a considerable amount of pus, the quantity of which was estimated to correspond with the quantity of albumin found. Kidney elements were not recognized. The cystoscope examination revealed the fundus and the trigon of the bladder and the ureteral openings to be of normal appearance. In the vertex of the bladder whitish excrescences were seen which covered an area of the size and shape of a quarter. The tips of these excrescences were dendritic and fluffy. The area was surrounded by mucosa raised in thick clumsy dark-red folds that were deprived of the normal gloss, and here and there a few submucous hemorrhagic patches were seen. In order to gain a clearer view of the base of this whitish centerpiece, finger pressure was exerted on the abdomen above the symphysis; the vertex of the bladder was inverted into the viscus and fluffy excrescences were seen to be located on top of a prominence that was surrounded by a circular ridge which gave a pronounced impression of rigidity. The dendritic excrescences were obviously phosphatic precipitations. The condition of solitary ulcer was excluded because such ulcers are sunk into the mucosa as if stamped with a die, while the bodily prominence stood out in relief; therefore the diagnosis was of an incrustated tumor. Such incrustations, as a rule, occur only on tumors that are "sick," that is, decaying on the surface, and only malignant tumors become "sick." The diagnosis, therefore, narrowed down to that of a malignant tumor of the vertex of the bladder surrounded by the inflammatory zone so frequently observed in the immediate vicinity of malignant bladder tumors. To increase the evidence the bladder was treated for a week with 20 per cent. argyrol instillations with no change in the condition or the cystoscopic appearance.

Operation.—The operative plan was the following: In order to avoid any handling of the growth during the operation with a subsequent inoculation of tumor cells into the healthy mucosa, after proper exposure the whole anterior aspect of the bladder was to be denuded of its peritoneal covering, and the top of the bladder clamped far enough down to insure the resection of the vertex vesicae in healthy tissue, the clamp being applied under the control of a cystoscope introduced into the bladder before the operation.

The tumor was extirpated by the following method: The bladder was flushed out and when the fluid returned clear the viscus was distended with 120 c.c. of sterile water, after which a Nitze examining cystoscope was introduced. The patient being under nitrous oxid-oxygen anesthesia, the bladder was exposed by a median incision and its anterior aspect was stripped bare, when it unexpectedly developed that the intended cystoscopic control of the clamp appeared to be entirely unnecessary. By palpation the insertion of the tumor and the surrounding zone of infiltration were demonstrated very clearly. The top of the bladder was picked up with an appendix forceps and drawn upward. By means of a curved intestinal clamp armed with rubber tubing the vertex of the bladder was clamped off beyond the zone of infiltration in a cephalo-caudal direction. The sequestrated part of the bladder was clipped off above the clamp and the first suture line was inserted. The clamp was then removed and a superseding suture line was laid. Muscle, fascia and skin were reunited save for a tiny drainage opening in the lower angle of the incision.

Postoperative History.—The patient began to urinate shortly after the operation and continued to do so up to the seventh day, at which time a small suprapubic fistula developed. For ten days, until the fistula closed, the urine flowed through the abdominal opening. Three weeks after the operation healing was complete. At this date the patient had to urinate rather frequently, the capacity of the bladder having been materially reduced by the extensive resection. Three months after the operation the patient was again able to retain 120 c.c. and cystoscopy at this date revealed that the inside of the bladder was apparently normal, the seat of the excision being marked by a slight distortion upward, evidently the result of the attachment of the vesical vertex to the abdominal wall. While the time which has elapsed since the operation is of course too short to allow a prediction of a permanent cure, still the operative result shows a technical success.

Macroscopically the specimen obtained by the operation was a disk 5 cm. in diameter. In the center the incrustated tumor was noted as a knob 2 cm. in diameter and 8 mm. high. Microscopically, the tumor proved to be a central carcinoma surrounded by an inflammatory area, and, so far as could be ascertained, the excision was made in non-carcinomatous tissue. The clamping off of the part of the bladder-wall to be resected was first suggested some fifteen years ago by a French surgeon, whose name, at present, I am unable to recall. Hagner some time ago tried to insulate a similarly located tumor by running sutures through the bladder-wall and beneath the base of the tumor under the control of the cystoscope.

BRAZIER'S DISEASE, BRASS-FOUNDER'S AGUE, OR ACUTE BRASS-POISONING *

CHARLES A. PFENDER, M.D., WASHINGTON, D. C.

For want of a better title I have given the name of "brazier's disease" to the syndrome about to be briefly described. The literature contains articles dealing with acute brass-poisoning, brass chills, brass-founder's ague, *fièvre des fondeurs*, *Staubfieber* and *Giessfieber*, all of which refer to the same symptom-complex. The symptoms are characteristic of acute brass-poisoning or zinc poisoning and occur only in workers who have to deal with molten zinc or brass in foundries. Brass is an alloy of copper and zinc in varying proportions. Until recently only founders were exposed to these fumes, but the modern development of industrial science, the intensive development of every known mechanical device has automatically created new vocations and given rise to diseases not hitherto encountered. The perfection of the acetylene-oxygen torch has led to a marvelous degree of autogenous welding and has remarkably facilitated the art of brazing; but from this "brazier's disease" has arisen.

Acute brass-poisoning, such as occurs in founders, was first recognized by Thackrah in England in 1830, and it has since been occasionally discussed by foreign writers. George M. Kober of this city was one of the few American writers who have had occasion to call attention to this disease. The exceedingly interesting report by Emery R. Hayhurst of Chicago, read before the section on hygiene of occupations of the Fifteenth International Congress on Hygiene and Demography in 1912, is the most comprehensive publication on this subject, deals with it in great detail and is well worth study. Hayhurst, however, confines his remarks exclusively to the disease among founders and makes no reference to it as occurring in any other branch of the brass industry. It is not unlikely that cases of this disease have frequently been encountered but have been confused with malaria, as the symptom-complex has much in common with that disease.

---

* Read before the Galen Society of Washington, D. C., Dec. 22, 1913.

Whenever an artificer has been exposed to the fumes of molten zinc or brass for several minutes or hours, depending largely on the ventilation of the workshop, he will experience a dry throat and a slight irritative dry cough which will cause him to seek fresh air if possible. As soon as he comes into the open he will experience a sudden chill, pain in the lungs and a sense of constriction of the chest accompanied by lassitude and a taste as of blood in the mouth. Sometimes nausea is present; occasionally vomiting occurs. Headache sets in and the chill grows more pronounced. Usually the patient will be compelled to lie down from twenty minutes to an hour after reaching fresh air. Fever, muscle cramps and joint pains are also present and the patient is the picture of misery. The symptoms terminate by a sort of pseudo-crisis with profuse perspiration, but the prostration may continue for several hours. Recovery is rapid and the patient is usually able to return to work the next day. The entire syndrome simulates that of an attack of acute malarial fever.

The case I observed occurred in a man, aged 23, an autogenous welder, forger and brazier, who had had frequent attacks which I interpreted as of malaria. He had spent a number of years in the South and had suffered from malarial nfection repeatedly. Blood examination failed to reveal the parasite, however. Quite by accident the patient observed that his attacks would occur only after he had been brazing, never after forging or welding with acetylene-oxygen torch. He would feel apparently well until he reached fresh air, when, as he expressed it, he was suddenly "knocked out," sometimes hardly able to get home. He would experience a general lassitude akin to exhaustion, pain in chest and rawness of lungs, and a taste as of blood in the mouth accompanied by a sharp rigor and general contraction of the muscles of the chest, arms and legs. Dyspnea was pronounced at times. When the attacks were severe—which was always the case when he had been exposed to the fumes for several hours—he would be literally stricken dumb, unable to move or to call for help. He describes the sensation as being "similar to lockjaw." The worst attack he had lasted four hours. His distress was so great that I resorted to morphin, 1/4 grain, and atropin, 1/100 grain which afforded relief. Sweat did not always follow the chills, nor was fever always present. and at no time did it exceed 101 F. The pulse was rapid and fairly strong, but he would tremble for hours after the paroxysm had subsided. He usually spent the next day or two out in the open air and then returned to work, apparently as well as ever. The repeated attacks reduced his weight from 136 to about 118 pounds within a few months.

As soon as I discovered that the brass fumes were the cause of all the trouble I cautioned him accordingly and recommended the installation of proper ventilation in the workshop. I advised him to engage in some other work between jobs instead of brazing continuously. He was given iron and arsenic for a long time and steadily improved until now he has regained his former weight and usual vigor. He has had several light attacks lately, but these were not sufficiently intense to force him to bed, and he was always in good condition after a night's rest. On several occasions he experienced great nervousness and a decided coarse tremor of the hands and arms and presented himself for treatment. Various remedies were resorted to, but none gave him the relief which was obtained by fifteen to thirty minutes' autocondensation treatment with about 600 to 800 milliamperes of the D'Arsonval current.

Hayhurst seems to think that fumes of molten brass or zinc form zinc carbonyl and that "the zinc is deposited as a slightly soluble compound in a very fine state of subdivision over the immense area of the respiratory surface," thus exerting its peculiar toxicity. It struck me that repeated attacks of this nature must necessarily have a disastrous effect on the pulmonary tissues after a while, just as is the case with stone-cutters, coal-miners, etc. A careful physical examination of the chest revealed nothing abnormal, but a radiograph of the chest showed that the fumes had effected many minor changes in the lungs, thus predisposing to tuberculosis or other infectious disease. Near the right hilum is a rarified area which is indicative of loss of lung tissue. It is probably a small cavity, the direct result of the death of pulmonary tissue which was caused by the inhaled toxic material. It is possible that this destruction accounts for the taste as of blood in the mouth.

I would suggest that more care be exercised in inquiring into a patient's occupation and the conditions under which he labors, especially if his disease is refractory to treatment.

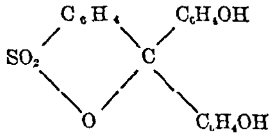
New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES."

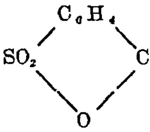
THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN, IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

PHENOLSULPHONEPHTHALEIN. — Phenolsulphonephthalein,



is a product of the interaction of phenol and sulphobenzoic acid anhydride,



differing from phenolphthalein in that a CO group of the latter is replaced by a SO_2 group.

Actions and Uses.—Solutions of phenolsulphonephthalein injected into the tissues are readily absorbed, and are excreted mainly in the urine. A very small amount is excreted by the feces.

Phenolsulphonephthalein is used for determining the functional activity of the kidney. When injected intramuscularly or intravenously it begins to be excreted in normal cases in from five to ten minutes. In case of a deficient functional activity, the first appearance of its secretion is delayed. In normal cases almost the total amount is excreted within two hours, from 60 to 80 per cent. Failure to excrete nearly the full amount within two hours indicates a deficient functional activity, and the degree of this functional deficiency may be estimated by the proportionate amount excreted within two hours. (See *Jour. Pharm. and Exper. Therap.*, 1910, i, 595, THE JOURNAL, Sept. 2, 1911, p. 811, *Arch. Int. Med.*, March, 1912, p. 284.)

Dosage.—(See above references.) One Cc. of a sterile solution, containing 0.006 Gm. phenolsulphonephthalein as the monosodium salt, is injected into the lumbar muscles. Great care must be taken that all of the solution is injected.

From twenty minutes to half an hour before administering the test, the patient is given from 200 to 400 Cc. of water in order to insure free urinary secretion; otherwise delayed time of appearance may be due to lack of secretion.

Under aseptic precautions a catheter is introduced and the bladder completely emptied or the patient is allowed voluning fluids, and fluids *in vitro* under different chemical conditions. That is, the liberation of free formaldehyd from hexamethylenamin depends on the excess hydrogen ion concentration of the fluid (true acidity).

This investigation is being continued so as to obtain more data, and a more complete report will be published later.

CLAMP RESECTION OF THE URINARY BLADDER

G. Kolischer, M.D., Chicago
Attending Genito-Urinary Surgeon to the Michael Reese and Maimonides Hospitals

The case which is the subject of this report is interesting from both a diagnostic and a technical point of view.

History.—The patient, a woman aged about 30, complains that during the last eight months she has been compelled to urinate frequently, especially on lying down, that each act of urination is rather painful and also that for the last six weeks the bladder has become the seat of spontaneous pains. The attending physician made a diagnosis of cystitis and tried to improve the condition by flushings of the bladder, which proved futile.

Examination.—I found, on examination, that the urine was cloudy, owing to the presence of a considerable amount of pus, the quantity of which was estimated to correspond with the quantity of albumin found. Kidney elements were not recognized. The cystoscope examination revealed the fundus and the trigon of the bladder and the ureteral openings to be of normal appearance. In the vertex of the bladder whitish excrescences were seen which covered an area of the size and shape of a quarter. The tips of these excrescences were dendritic and fluffy. The area was surrounded by mucosa raised in thick clumsy dark-red folds that were deprived of the normal gloss, and here and there a few submucous hemorrhagic patches were seen. In order to gain a clearer view of the base of this whitish centerpiece, finger pressure was exerted on the abdomen above the symphysis; the vertex of the bladder was inverted into the viscus and fluffy excrescences were seen to be located on top of a prominence that was surrounded by a circular ridge which gave a pronounced impression of rigidity. The dendritic excrescences were obviously phosphatic precipitations. The condition of solitary ulcer was excluded because such ulcers are sunk into the mucosa as if stamped with a die, while the bodily prominence stood out in relief; therefore the diagnosis was of an incrustated tumor. Such incrustations, as a rule, occur only on tumors that are "sick," that is, decaying on the surface, and only malignant tumors become "sick." The diagnosis, therefore, narrowed down to that of a malignant tumor of the vertex of the bladder surrounded by the inflammatory zone so frequently observed in the immediate vicinity of malignant bladder tumors. To increase the evidence the bladder was treated for a week with 20 per cent. argyrol instillations with no change in the condition or the cystoscopic appearance.

Operation.—The operative plan was the following: In order to avoid any handling of the growth during the operation with a subsequent inoculation of tumor cells into the healthy mucosa, after proper exposure the whole anterior aspect of the bladder was to be denuded of its peritoneal covering, and the top of the bladder clamped far enough down to insure the resection of the vertex vesicae in healthy tissue, the clamp being applied under the control of a cystoscope introduced into the bladder before the operation.

The tumor was extirpated by the following method: The bladder was flushed out and when the fluid returned clear the viscus was distended with 120 c.c. of sterile water, after which a Nitze examining cystoscope was introduced. The patient being under nitrous oxid-oxygen anesthesia, the bladder was exposed by a median incision and its anterior aspect was stripped bare, when it unexpectedly developed that the intended cystoscopic control of the clamp appeared to be entirely unnecessary. By palpation the insertion of the tumor and the surrounding zone of infiltration were demonstrated very clearly. The top of the bladder was picked up with an appendix forceps and drawn upward. By means of a curved intestinal clamp armed with rubber tubing the vertex of the bladder was clamped off beyond the zone of infiltration in a cephalo-caudal direction. The sequestrated part of the bladder was clipped off above the clamp and the first suture line was inserted. The clamp was then removed and a superseding suture line was laid. Muscle, fascia and skin were reunited save for a tiny drainage opening in the lower angle of the incision.

Postoperative History.—The patient began to urinate shortly after the operation and continued to do so up to the seventh day, at which time a small suprapubic fistula developed. For ten days, until the fistula closed, the urine flowed through the abdominal opening. Three weeks after the operation healing was complete. At this date the patient had to urinate rather frequently, the capacity of the bladder having been materially reduced by the extensive resection. Three months after the operation the patient was again able to retain 120 c.c. and cystoscopy at this date revealed that the inside of the bladder was apparently normal, the seat of the excision being marked by a slight distortion upward, evidently the result of the attachment of the vesical vertex to the abdominal wall. While the time which has elapsed since the operation is of course too short to allow a prediction of a permanent cure, still the operative result shows a technical success.

Macroscopically the specimen obtained by the operation was a disk 5 cm. in diameter. In the center the incrustated tumor was noted as a knob 2 cm. in diameter and 8 mm. high. Microscopically, the tumor proved to be a central carcinoma surrounded by an inflammatory area, and, so far as could be ascertained, the excision was made in non-carcinomatous tissue. The clamping off of the part of the bladder-wall to be resected was first suggested some fifteen years ago by a French surgeon, whose name, at present, I am unable to recall. Hagner some time ago tried to insulate a similarly located tumor by running sutures through the bladder-wall and beneath the base of the tumor under the control of the cystoscope.

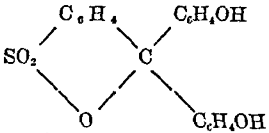
New and Nonofficial Remedies

The following additional articles have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association. Their acceptance has been based largely on evidence supplied by the manufacturer or his agent and in part on investigation made by or under the direction of the Council. Criticisms and corrections are asked for to aid in the revision of the matter before publication in the book "New and Nonofficial Remedies."

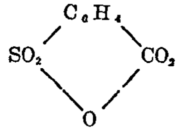
The Council desires physicians to understand that the acceptance of an article does not necessarily mean a recommendation, but that, so far as known, it complies with the rules adopted by the Council.

W. A. Puckner, Secretary.

PHENOLSULPHONEPHTHALEIN. — Phenolsulphonephthalein,



is a product of the interaction of phenol and sulphobenzoic acid anhydride,



differing from phenolphthalein in that a CO group of the latter is replaced by a SO_2 group.

Actions and Uses.—Solutions of phenolsulphonephthalein injected into the tissues are readily absorbed, and are excreted mainly in the urine. A very small amount is excreted by the feces.

Phenolsulphonephthalein is used for determining the functional activity of the kidney. When injected intramuscularly or intravenously it begins to be excreted in normal cases in from five to ten minutes. In case of a deficient functional activity, the first appearance of its secretion is delayed. In normal cases almost the total amount is excreted within two hours, from 60 to 80 per cent. Failure to excrete nearly the full amount within two hours indicates a deficient functional activity, and the degree of this functional deficiency may be estimated by the proportionate amount excreted within two hours. (See *Jour. Pharm. and Exper. Therap.*, 1910, i, 595, The Journal, Sept. 2, 1911, p. 811, *Arch. Int. Med.*, March, 1912, p. 284.)

Dosage.—(See above references.) One Cc. of a sterile solution, containing 0.006 Gm. phenolsulphonephthalein as the monosodium salt, is injected into the lumbar muscles. Great care must be taken that all of the solution is injected.

From twenty minutes to half an hour before administering the test, the patient is given from 200 to 400 Cc. of water in order to insure free urinary secretion; otherwise delayed time of appearance may be due to lack of secretion.

Under aseptic precautions a catheter is introduced and the bladder completely emptied or the patient is allowed voluntarily to do so. Noting the time, 1 Cc. of a carefully prepared solution of the phenolsulphonephthalein containing 6 mg. to the cubic centimeter is accurately administered intramuscularly or intravenously by means of an accurately graduated syringe.

The urine is allowed to drain into a test-tube in which has been placed a drop of 25 per cent. sodium hydroxid solution and the time of the appearance of the first faint pinkish tinge is noted.

In patients without urinary obstruction the catheter is withdrawn at the time of the appearance of the drug in the urine, and the patient is instructed to void into a receptacle at the end of one hour and into a second receptacle at the end of the second hour.

When the passing of a catheter is disagreeable and no urinary retention is present its use can be dispensed with and the time of appearance of the drug disregarded.

The urine collected is made alkaline with a 25 per cent. solution of sodium hydroxid and then diluted to 1 liter. The solution is thoroughly mixed and a small filtered portion taken to compare with the standard which is used for all of these estimations. Comparison is made in a colorimeter, a special form of which has been devised for this purpose.

Phenolsulphonephthalein is a bright red crystalline powder, slightly soluble in water and in alcohol with formation of a yellow solution; it is insoluble in ether. It is soluble in dilute alkalies with formation of a solution whose color is a purer red than alkaline phenolphthalein, while a strongly alkaline solution is purple. In solution it is sensitive to carbonic acid just as phenolphthalein is. It is readily soluble in sodium carbonate solution and shows stronger acid properties than any of the related phthaleins. The substance at first has a slightly sweetish taste which changes to a disagreeable bitter taste.

Proprietary preparation:

PHENOLSULPHONEPHTHALEIN—H. W. & Co.—Phenolsulphonephthalein made by a special process and said to be exceptionally pure.

Manufactured by Hynson, Westcott & Co., Baltimore, Md. No U. S. patents or trademarks.

Phenolsulphonephthalein Ampoules.—Ampules containing 1 Cc. of a sterile solution of 0.006 Gm. phenolsulphonephthalein, in the form of the monosodium salt.

STERILE AMPOULES OF MERCURY SALICYLATE.—This dosage form of an accepted non-proprietary article has been accepted.

Each ampule contains 0.06 gm. (1 grain) of mercuric salicylate suspended in a mixture of vegetable fats which are solid at 34.4 C. (94 F.) but liquid at body temperature.

Dosage.—The ampule is immersed in warm water until the fat is liquefied, agitated, opened, and the contents injected through a 20-gage needle. This preparation should not be injected intravenously.

Prepared by Hynson, Westcott and Co., Baltimore, Md.

SALVARSAN—EHRLICH, SUSPENSION IN AMPOULES.—This preparation has been accepted for inclusion with the appendix to New and Nonofficial Remedies.

Each ampule contains 0.10 gm. (1½ grains) of salvarsan suspended in a mixture of vegetable fats, which are solid at 34.4 C. (94 F.), but liquid at body temperature.

Dosage.—The ampule is immersed in warm water until the fat becomes liquefied, agitated, opened and the contents injected through a 20-gage needle. This preparation should not be injected intravenously.

Prepared by Hynson, Westcott and Co., Baltimore, Md.

NEOSALVARSAN—EHRLICH, SUSPENSION IN AMPOULES.—This preparation has been accepted for inclusion with the appendix to New and Nonofficial Remedies.

Each ampule contains 0.15 gm. (2 3/10 grains) of neosalvarsan suspended in a mixture of vegetable fats which are solid at 34.4 C. (94 F.), but liquid at body temperature.

Dosage.—The ampule is immersed in warm water until the fat is liquefied, agitated, opened, and the contents injected through a 20-gage needle. This preparation should not be injected intravenously.

Prepared by Hynson, Westcott and Co., Baltimore, Md.

Therapeutics

CALCIUM

(Concluded from page 207)

CALCIUM IN PREGNANCY

Many investigations have shown that during pregnancy and the puerperium there is a diminished amount of calcium in the blood. A large amount of calcium is needed during pregnancy for the growth of the fetus, and immediately after parturition the diminished amount of calcium in the blood is probably due to its being excreted in the milk. It has been suggested[5] that this withdrawal of calcium may cause a fatty infiltration, and later, fatty degeneration of the liver-cells, and therefore a disturbed function of the liver. If this be true, it would seemingly contra-indicate the administration of chloroform during labor if calcium were thought to be deficient, the tendency of chloroform to cause liver disturbances being now well recognized.

If the calcium is much diminished in the blood, the parturient woman may have considerable uterine hemorrhage. This might not be a disadvantage, if a deficient liver caused toxemias of the blood and a tendency to eclampsia. Free uterine hemorrhage is of advantage as a preventive of eclampsia during and after parturition.

While some more recent investigations by Linzenmeier[6] have shown that in the blood of some pregnant women, at least, there is an increased proportion of calcium, and that there may not be a decrease of calcium during eclampsia, the need of the body for an extra amount of calcium during pregnancy is unquestionable. The corollary to the proposition that a lime deficiency is likely to be always more or less in evidence during pregnancy, and that it is macroscopically shown by the decay of the teeth during this condition, is that pregnant women should be given calcium salts medicinally and considerable amounts of foods rich in calcium.

It is also quite possible that, if the mother has a deficient supply of lime, the fetus may start its life handicapped by a lime deficiency, its bones may not grow properly, its teeth may not erupt properly, and even later the teeth may decay quickly. Be this supposition correct or incorrect, the mother should certainly receive foods rich in calcium during pregnancy and during lactation. These foods are cheese, milk, yolk of egg, spinach, beans, peas and many fruits. Bread, the white of egg, rice and potatoes contain little calcium, and meat a very small amount.

LIME IN RICKETS AND OSTEOMALACIA

There is no question of the fact that lime is deficient in these diseases. It is only in rare instances, however, that the patients are taking food that is seriously deficient in calcium; usually there is, instead, a faulty calcium metabolism. Therefore, the administration of calcium as a drug to these patients does not give satisfactory therapeutic results. It seems to be a fact that bottle-fed infants, even when given cow's milk, are more likely to suffer from rickets than is the breast-fed infant. It is quite probable that some internal secretion necessary for perfect nutrition is secreted in the mother's milk, may be absent in cow's milk, and hence bottle-fed children may not receive it. It is also quite probable that some children, even if breast-fed, suffer from calcium malnutrition because of defective secreting glands in the mother. Also, one or more of the glands of internal secretion in such defective children may be acting insufficiently.

[6] Linzenmeier, G.: Der Kalkgehalt des Blutes in der Schwangerschaft, Zentralbl. f. Gynäk., June 28, 1913, p. 959.

Many infants who do not develop rickets have disorders of digestion, and these are markedly benefited by the administration of calcium as a medicine. On the other hand, it can do no harm to administer calcium to rachitic patients. Small doses of pituitary extract may be of benefit in this disease. Thymus feeding has apparently failed to be of value.

LIME IN SPASMOPHILIA, TETANY AND INFANTILE CONVULSIONS

This subject has been recently discussed[7] in this department. Suffice it to say that disturbances of the parathyroid glands are more or less closely related to these conditions, and it has been found that the administration of calcium is as beneficial as that of parathyroid substance is. Hence calcium is indicated as a part of the treatment in all of these conditions. Even gastric tetany has been benefited by the administration of the calcium salts.

CALCIUM AND ARTERIOSCLEROSIS

Recently, Scandola[8] has stated his belief that in arteriosclerosis there is a retention of calcium in the tissues, on ordinary diets, and he believes that this retained calcium is likely to promote the progress of the disease and be an important factor in the deposition of calcium salts in the arterial system. He finds that nothing promotes the elimination of calcium more than the use of foods that contain little calcium, such as bread, potato, rice and meat. Cheese, milk, eggs and *many fruits should be avoided.*

PREPARATIONS OF CALCIUM

Calcii Chloridum, U. S. P. — This is a white salt, very deliquescent, soluble in water, an irritant, with a sharp, salty taste. It has many disadvantages and no special advantages over calcium lactate; therefore, the lactate should be the salt most frequently used. The dose of calcium chlorid is given in the Pharmacopeia as 0.50 gm. (7½ grains), but the dose of 0.30 gm. (5 grains) is sufficient. It is generally administered three times a day, after meals, and may be given every three hours for several doses, if deemed advisable. As it is irritant, it should always be given either on an empty stomach or dissolved in some thick syrup and water, or in glycerin.

		Gm. or c c.		
℞	Calcii chloridi	6		gr. lxxx
	Glycerini	50	or	fl. ℥iss
	Aqua menthae piperitae q. s. ad	100		fl. ℥iii

M. Sig.: A teaspoonful, in plenty of water, three times a day, after meals.

Syrup of tolu may be substituted for the glycerin. Or syrupus calcis, U. S. P. (a syrupy preparation of calcium oxid) may be administered in 2 c.c. (30 minim) doses.

Liquor Calcis, U. S. P. — Lime-water is a bland, non-irritant watery solution of lime (calcium oxid), used internally as a mild antacid. Probably very little calcium, either in this preparation or in the syrup of lime, is absorbed, and the action of these preparations is largely on the bowels. They tend to cause constipation, and are often of benefit (particularly the lime-water) in diarrheas, especially in infants. Lime-water is often added to milk, not only to increase the calcium content, but to prevent the acid of the stomach from causing rapid coagulation with the formation of large curds, since small curds are more easily digested. As lime-water is a harmless preparation, the amount added to an infant's milk should not be too small, and one, two or three teaspoonfuls may be added to each or to every other feeding, dependent on the age and the condition of the child. Externally, lime-water in equal combination with linseed oil forms linimentum calcis, U. S. P. (carron oil), a soothing alkaline protective, which has been used for many years as a sedative for the skin, especially in burns.

Calcii Lactas. N. N. R. — Calcium lactate is a calcium salt of lactic acid. It is much less irritant than the chlorid, and is valuable when a calcium salt is indicated. It occurs as an odorless, tasteless powder, not very soluble in water, requiring twenty parts of cold water to dissolve it. The dose is about 0.30 gm. (5 grains). It is best administered in powder, taken well diluted, or with milk or after meals.

Calcii Glycerophosphas, N. N. R.—Calcium glycerophosphate is the normal calcium salt of glycerophosphoric acid. It is a fine white powder, without odor or taste, practically insoluble in water, and is best administered in powder, tablet or capsule. The average dose is 0.30 gm. (5 grains) three times a day, after meals. This is probably the best salt of calcium to administer for nutritional results.

Compound syrups of glycerophosphates, as *calcii hypophosphis,* U. S. P., and *syrupus hypophosphitum compositus,* U. S. P., are superfluous preparations.

The *precipitated calcium carbonate* and *prepared chalk* may be used internally, but are most used externally. They are mild alkalies, and tend to cause constipation. The official chalk mixture (*mistura cretae,* U. S. P.) is a harmless simple preparation. If it is desired to give a child chalk, however, it had better be given in powder form and added to whatever nutriment (as barley water, or milk), the child may be receiving. Chalk mixture must be well shaken, and the dose the child would receive is indefinite.

The precipitated calcium phosphate is a preparation that has been greatly used and recommended in bone disturbances. It is an insoluble, white, tasteless and odorless powder. The Pharmacopeial dose is 1 gm. (15 grains). Unfortunately, calcium phosphate cannot be transferred as such from the intestine to bone structure; the calcium must be entirely metabolized in whatever form it is offered, and therefore this powder in its large (bulky) doses is not needed. The glycerophosphate is a better preparation.

Rat Prevention in Cities.—Sewers harbor and provide the means for the spread of rats. The rat-proofing of the city cannot be accomplished until the sewers of the city are made practically rat-proof. Rats enter and leave sewers principally *through openings in corner catch-basins.* Corner catch-basins are unnecessary in general sewer construction, and should be installed *only* when *conditions* require them. Mechanical and water-traps are unnecessary in properly designed catch-basins and should be omitted. Catch-basins, unless designed to permit prompt and direct discharge of sediment into the sewer, should be cleaned at least three times a year. Water-sealing traps should be frequently replaced and oiled to prevent development of mosquitoes.—Friench Simpson, *Pub. Health Rep.*

[8] Scandola: Gaz. d. Osp., Sept. 7, 1913, p. 1111.

tarily to do so. Noting the time, 1 Cc. of a carefully prepared solution of the phenolsulphonephthalein containing 6 mg. to the cubic centimeter is accurately administered intramuscularly or intravenously by means of an accurately graduated syringe.

The urine is allowed to drain into a test-tube in which has been placed a drop of 25 per cent. sodium hydroxid solution and the time of the appearance of the first faint pinkish tinge is noted.

In patients without urinary obstruction the catheter is withdrawn at the time of the appearance of the drug in the urine, and the patient is instructed to void into a receptacle at the end of one hour and into a second receptacle at the end of the second hour.

When the passing of a catheter is disagreeable and no urinary retention is present its use can be dispensed with and the time of appearance of the drug disregarded.

The urine collected is made alkaline with a 25 per cent. solution of sodium hydroxid and then diluted to 1 liter. The solution is thoroughly mixed and a small filtered portion taken to compare with the standard which is used for all of these estimations. Comparison is made in a colorimeter, a special form of which has been devised for this purpose.

Phenolsulphonephthalein is a bright red crystalline powder, slightly soluble in water and in alcohol with formation of a yellow solution; it is insoluble in ether. It is soluble in dilute alkalies with formation of a solution whose color is a purer red than alkaline phenolphthalein, while a strongly alkaline solution is purple. In solution it is sensitive to carbonic acid just as phenolphthalein is. It is readily soluble in sodium carbonate solution and shows stronger acid properties than any of the related phthaleins. The substance at first has a slightly sweetish taste which changes to a disagreeable bitter taste.

Proprietary preparation:

PHENOLSULPHONEPHTHALEIN—H. W. & Co.—Phenolsulphonephthalein made by a special process and said to be exceptionally pure.

Manufactured by Hynson, Westcott & Co., Baltimore, Md. No U. S. patents or trademarks.

Phenolsulphonephthalein Ampoules.—Ampules containing 1 Cc. of a sterile solution of 0.006 Gm. phenolsulphonephthalein, in the form of the monosodium salt.

STERILE AMPOULES OF MERCURY SALICYLATE.—This dosage form of an accepted non-proprietary article has been accepted.

Each ampule contains 0.06 gm. (1 grain) of mercuric salicylate suspended in a mixture of vegetable fats which are solid at 34.4 C. (94 F.) but liquid at body temperature.

Dosage.—The ampule is immersed in warm water until the fat is liquefied, agitated, opened, and the contents injected through a 20-gage needle. This preparation should not be injected intravenously.

Prepared by Hynson, Westcott and Co., Baltimore, Md.

SALVARSAN—EHRLICH, SUSPENSION IN AMPOULES.—This preparation has been accepted for inclusion with the appendix to New and Nonofficial Remedies.

Each ampule contains 0.10 gm. (1½ grains) of salvarsan suspended in a mixture of vegetable fats, which are solid at 34.4 C. (94 F.), but liquid at body temperature.

Dosage.—The ampule is immersed in warm water until the fat becomes liquefied, agitated, opened and the contents injected through a 20-gage needle. This preparation should not be injected intravenously.

Prepared by Hynson, Westcott and Co., Baltimore, Md.

NEOSALVARSAN—EHRLICH, SUSPENSION IN AMPOULES.—This preparation has been accepted for inclusion with the appendix to New and Nonofficial Remedies.

Each ampule contains 0.15 gm. (2 3/10 grains) of neosalvarsan suspended in a mixture of vegetable fats which are solid at 34.4 C. (94 F.), but liquid at body temperature.

Dosage.—The ampule is immersed in warm water until the fat is liquefied, agitated, opened, and the contents injected through a 20-gage needle. This preparation should not be injected intravenously.

Prepared by Hynson, Westcott and Co., Baltimore, Md.

THE CAUSATION OF CERTAIN ANIMAL TUMORS

The discovery of ultramicroscopic agents of infection in the form of so-called filterable viruses came at a period in the study of certain diseases when the hope of finding a responsible micro-organism, to the existence of which all the evidence strongly pointed, began to approach the stage of despair. The long story of unsuccessful attempts to isolate and cultivate an organism responsible for yellow fever, and the more recent experiences with the causative agent in anterior poliomyelitis which is now known to pass through filters that were at one time relied on to obstruct entirely the passage of pathogenic organisms, are fresh in the minds of those who have followed the progress of the study of infectious diseases. Without committing us to any etiologic theory of cancer, the preceding fragments of the history of medical science must be kept in mind whenever we are informed that micro-organisms can have no importance in the causation of malignant growths.

The persistent assertions that the factors already established are sufficient to explain the origin of cancer express the convictions of pathologists who have primarily been interested in the careful study of the structure of pathologic tissues. The repeated failures to substantiate the constant presence of parasitic micro-organisms in human cancer have led to an unduly skeptical attitude toward everything that smacks of microbiotic possibilities. The recent experiments of Peyton Rous of the Rockefeller Institute for Medical Research have supplied the proof of filterable agencies which can induce body-cells in animals to proliferate in such a manner that certain kinds of animal cancer result. To the two chicken-tumors for which Rous and his collaborators have found the cause in filterable entities, a third has now been added.[1] These types of spontaneous chicken-tumors thus far discovered include a pure spindle-cell sarcoma, an osteochondrosarcoma and a peculiar spindle-cell sarcoma fissured by blood-sinuses. Despite the fact that the three transferable neoplasms are very unlike both histologically and in their general behavior, the entities causing them appear to have much in common. Not infrequently thus far the filtrates prepared under the best conditions from malignant material have proved entirely innocuous. This is doubtless due to the narrow mechanical limits within which the causative agents are filterable. When growths are engendered by a Berkefeld filtrate passed through cylinders which are impermeable at the same test to small bacteria, they have the distinctive characters of the strain of tumor which furnished the material for filtration. Two of these new causative agents retain their activity in tumor-tissue that has been dried or glycerinated. All are strikingly dependent for their action on derangement of the tissue with which they are brought into contact. When this factor is supplied, for example, by the addition of kieselguhr powder to the filtrate, the percentage of fowls that develop tumors is much increased, and the growths themselves appear sooner and enlarge more rapidly. The kieselguhr, injected alone, does not cause tumors. A limpid tumor-filtrate injected into the breast-muscle finds its point of action in the track of the injecting needle, and there results a discrete growth from one center. When powdered kieselguhr has been added, the growth is multicentric, and appears all at once as a mass of coalescing foci. In fowls inoculated intravenously with a chicken-tumor filtrate the tumors have been found to arise at sites of tissue derangement.

The newer researches strongly suggest that the causative agents of these animal tumors are of about the same size and of the same natural class. We endorse the modest conclusion of the Rockefeller Institute investigators that "it is perhaps not too much to say that their recognition points to the existence of a new group of entities which cause in chickens neoplasms of diverse character." This is, indeed, a step in the direction of scientific progress.

THE PATHOGENICITY OF AMEBAS

At the biennial conference of the Far Eastern Association for Tropical Medicine, held recently at Saigon, Walker and Sellards[1] reported some interesting results of the experimental feeding of different species of amebas to human beings. Their work was unique not only in the number of comparative tests made of different species, but also in the thorough determination of the species of organism fed.

In all, sixty tests were made, embracing twenty feedings of artificially cultivated amebas representing thirteen strains and eight species, twenty of *Entamoeba coli* and twenty of *Entamoeba histolytica*. In the first series — the feeding of cultivable species of amebas — it was usually possible to recover the organisms on suitable mediums during the first few days, but not subsequently, nor did later microscopic examination establish their presence. In none of these cases was there a resultant dysentery. Of the subjects fed with *Entamoeba coli*, seventeen became parasitized at the first feeding, after incubation periods of from one to eleven days. None of the seventeen developed dysenteric symptoms, nor was it possible in any of them to obtain the organism by means of cultivation methods. Of the twenty volunteers fed with *Entamoeba histolytica*, seventeen became parasitized after the first feeding, one required three feedings to become parasitized, and the two remaining were held as controls. The incubation period in these seventeen cases varied from one to forty-four days; the incubation period of the dysenteric symptoms which developed in four of the parasitized subjects, was on the average sixty-five days, the shortest being twenty, the longest ninety-four. In the stools of those fed only with motile *Entamoeba histolytica*, protected artificially from the gastric juice, it was possible to find exclusively encysted *Entamoeba tetragena*, and vice versa, while in one case, of a man fed only with tetragena cysts, there were alternations, several times repeated, of tetragena cysts and motile *Entamoeba histolytica*. Of peculiar significance are the facts that no cases of dysentery developed in men who ingested *Entamoeba histolytica* from an acute case of entamebic dysentery or from one of liver abscess, while all the successful productions of dysentery resulted from the feeding of *Entamoeba histolytica* from the normal stools of "carriers." Artificial cultivation of *Entamoeba histolytica* was in no case found possible.

[1] Walker and Sellards: Experimental Entamoebic Dysentery, Third Biennial Conference, Far Eastern Association of Tropical Medicine

From the foregoing results Walker and Sellards conclude that: 1. The cultivable amebas not only are nonpathogenic to man, but are also incapable of parasitic infestation of the human alimentary tract. The fact of their occasional cultivation from human stools they consider is due either to cultural contaminations or to the passage of accidentally ingested encysted amebas. 2. *Entamoeba coli*, while being an obligative parasite, is non-pathogenic, and is not concerned in the causation of endemic tropical dysentery. 3. *Entamoeba histolytica*, like *Entamoeba coli*, is an obligative parasite, and as such is the causative factor in entamebic dysentery. Further, *Entamoeba histolytica* and *Entamoeba tetragena* are simply variant forms in the life cycle of the same organism.

In the way of practical results, Walker and Sellards point out that with the exclusion of *Entamoeba coli* as a cause of dysentery, the indiscriminate treatment of all persons showing entamebas in their stools becomes unwarranted, and that a recognition of the specific *Entamoeba histolytica* should be an essential precedent for such treatment. They consider it probable that the motile forms found in the acute stages of the disease have little to do with its transmission, which they believe is probably due to the ingestion of the more resistant encysted forms derived from "carriers." Prophylaxis, therefore, in their opinion, should be directed toward (1) the identification of "carriers" by the systematic examination of stools of all persons whose history or occupation would fit them for such a rôle; (2) the sanitary disposal of feces; (3) treatment of "carriers," controlled by stool examinations, and (4) precautionary examination of the stools of all persons living in endemic regions, in the effort to recognize the organism while the disease is still in the sometimes prolonged period of incubation.

GORGAS APPOINTED SURGEON-GENERAL

The announcement that the President has nominated Col. William C. Gorgas as Surgeon-General of the Army of the United States, with the rank of brigadier-general, will be received with approval, not only by the medical profession, but also by the public. Probably not since the days of the Civil War has it been possible for a President to make an appointment that will cause so much general satisfaction. The people of the United States justly regard the construction of the Panama Canal as one of the great achievements in our national history. From the point of view of the constructing engineer, its completion, in advance of the estimated time and at less than the estimated cost, is a triumph for American engineering skill, for the Army engineer and for West Point training.

For his masterly ability as an organizer and administrator, highest praise is due to Colonel Goethals, and any reward which Congress or the President may see fit to confer on him will be well deserved; but the mechanical construction of the Panama Canal differs from other engineering feats only in size. The work of the Sanitary Department under Colonel Gorgas has not only been the greatest task of sanitation that has ever been undertaken, but it is also unique and epoch-making. For the first time in human history a region which, since the earliest traditions of civilization, has been regarded as a plague spot in which it was impossible for civilized man to live and work, has been converted into a place fitted for enjoyable habitation and labor, with a death-rate below that of the most modern cities. Such an achievement is not only of the most vital importance in making possible the construction of the canal, but it also has a broader and a far greater significance. It is a practical demonstration on a large scale of the possibilities of preventive medicine and of the application of scientific discoveries of the past fifty years in the prevention of disease.

While the general public will most readily grasp the importance of this work on account of its humanitarian aspect, the world of business has been convinced, as never

THE CAUSATION OF CERTAIN ANIMAL TUMORS

The discovery of ultramicroscopic agents of infection in the form of so-called filterable viruses came at a period in the study of certain diseases when the hope of finding a responsible micro-organism, to the existence of which all the evidence strongly pointed, began to approach the stage of despair. The long story of unsuccessful attempts to isolate and cultivate an organism responsible for yellow fever, and the more recent experiences with the causative agent in anterior poliomyelitis which is now known to pass through filters that were at one time relied on to obstruct entirely the passage of pathogenic organisms, are fresh in the minds of those who have followed the progress of the study of infectious diseases. Without committing us to any etiologic theory of cancer, the preceding fragments of the history of medical science must be kept in mind whenever we are informed that micro-organisms can have no importance in the causation of malignant growths.

The persistent assertions that the factors already established are sufficient to explain the origin of cancer express the convictions of pathologists who have primarily been interested in the careful study of the structure of pathologic tissues. The repeated failures to substantiate the constant presence of parasitic micro-organisms in human cancer have led to an unduly skeptical attitude toward everything that smacks of microbiotic possibilities. The recent experiments of Peyton Rous of the Rockefeller Institute for Medical Research have supplied the proof of filterable agencies which can induce body-cells in animals to proliferate in such a manner that certain kinds of animal cancer result. To the two chicken-tumors for which Rous and his collaborators have found the cause in filterable entities, a third has now been added.[1] These types of spontaneous chicken-tumors thus far discovered include a pure spindle-cell sarcoma, an osteochondrosarcoma and a peculiar spindle-cell sarcoma fissured by blood-sinuses. Despite the fact that the three transferable neoplasms are very unlike both histologically and in their general behavior, the entities causing them appear to have much in common. Not infrequently thus far the filtrates prepared under the best conditions from malignant material have proved entirely innocuous. This is doubtless due to the narrow mechanical limits within which the causative agents are filterable. When growths are engendered by a Berkefeld filtrate passed through cylinders which are impermeable at the same test to small bacteria, they have the distinctive characters of the strain of tumor which furnished the material for filtration. *Two of these new causative agents retain their* activity in tumor-tissue that has been dried or glycerinated. All are strikingly dependent for their action on derangement of the tissue with which they are brought into contact. When this factor is supplied, for example, by the addition of kieselguhr powder to the filtrate, the percentage of fowls that develop tumors is much increased, and the growths themselves appear sooner and enlarge more rapidly. The kieselguhr, injected alone, does not cause tumors. A limpid tumor-filtrate injected into the breast-muscle finds its point of action in the track of the injecting needle, and there results a discrete growth from one center. When powdered kieselguhr has been added, the growth is multicentric, and appears all at once as a mass of coalescing foci. In fowls inoculated intravenously with a chicken-tumor filtrate the tumors have been found to arise at sites of tissue derangement.

The newer researches strongly suggest that the causative agents of these animal tumors are of about the same size and of the same natural class. We endorse the modest conclusion of the Rockefeller Institute investigators that "it is perhaps not too much to say that their recognition points to the existence of a new group of entities which cause in chickens neoplasms of diverse character." This is, indeed, a step in the direction of scientific progress.

THE PATHOGENICITY OF AMEBAS

At the biennial conference of the Far Eastern Association for Tropical Medicine, held recently at Saigon, Walker and Sellards[1] reported some interesting results of the experimental feeding of different species of amebas to human beings. Their work was unique not only in the number of comparative tests made of different species, but also in the thorough determination of the species of organism fed.

In all, sixty tests were made, embracing twenty feedings of artificially cultivated amebas representing thirteen strains and eight species, twenty of *Entamoeba coli* and twenty of *Entamoeba histolytica*. In the first series — the feeding of cultivable species of amebas — it was usually possible to recover the organisms on suitable mediums during the first few days, but not subsequently, nor did later microscopic examination establish their presence. In none of these cases was there a resultant dysentery. Of the subjects fed with *Entamoeba coli*, seventeen became parasitized at the first feeding, after incubation periods of from one to eleven days. None of the seventeen developed dysenteric symptoms, nor was it possible in any of them to obtain the organism by means of cultivation methods. Of the twenty volunteers fed with *Entamoeba histolytica;* seventeen became parasitized after the first feeding, one required three feedings to become parasitized, and the two remaining were held as controls. The incubation period in these seventeen cases varied from one to forty-four days; the incubation period of the dysenteric symptoms which developed in four of the parasitized subjects, was on the average sixty-five days, the shortest being twenty, the longest ninety-four. In the stools of those fed only with motile *Entamoeba histolytica*, protected artificially from the gastric juice, it was possible to find exclusively encysted *Entamoeba tetragena*, and vice versa, while in one case, of a man fed only with tetragena cysts, there were alternations, several times repeated, of tetragena cysts and motile *Entamoeba histolytica*. Of peculiar significance are the facts that no cases of dysentery developed in men who ingested *Entamoeba histolytica* from an acute case of entamebic dysentery or from one of liver abscess, while all the successful productions of dysentery resulted from the feeding of *Entamoeba histolytica* from the normal stools of "carriers." Artificial cultivation of *Entamoeba histolytica* was in no case found possible.

[1] Walker and Sellards: Experimental Entamoebic Dysentery, Third Biennial Conference, Far Eastern Association of Tropical Medicine

From the foregoing results Walker and Sellards conclude that: 1. The cultivable amebas not only are nonpathogenic to man, but are also incapable of parasitic infestation of the human alimentary tract. The fact of their occasional cultivation from human stools they consider is due either to cultural contaminations or to the passage of accidentally ingested encysted amebas. 2. *Entamoeba coli*, while being an obligative parasite, is non-pathogenic, and is not concerned in the causation of endemic tropical dysentery. 3. *Entamoeba histolytica*, like *Entamoeba coli*, is an obligative parasite, and as such is the causative factor in entamebic dysentery. Further, *Entamoeba histolytica* and *Entamoeba tetragena* are simply variant forms in the life cycle of the same organism.

In the way of practical results, Walker and Sellards point out that with the exclusion of *Entamoeba coli* as a cause of dysentery, the indiscriminate treatment of all persons showing entamebas in their stools becomes unwarranted, and that a recognition of the specific *Entamoeba histolytica* should be an essential precedent for such treatment. They consider it probable that the motile forms found in the acute stages of the disease have little to do with its transmission, which they believe is probably due to the ingestion of the more resistant encysted forms derived from "carriers." Prophylaxis, therefore, in their opinion, should be directed toward (1) the identification of "carriers" by the systematic examination of stools of all persons whose history or occupation would fit them for such a rôle; (2) the sanitary disposal of feces; (3) treatment of "carriers," controlled by stool examinations, and (4) precautionary examination of the stools of all persons living in endemic regions. in the effort to recognize the organism while the disease is still in the sometimes prolonged period of incubation.

GORGAS APPOINTED SURGEON-GENERAL

The announcement that the President has nominated Col. William C. Gorgas as Surgeon-General of the Army of the United States, with the rank of brigadier-general, will be received with approval, not only by the medical profession, but also by the public. Probably not since the days of the Civil War has it been possible for a President to make an appointment that will cause so much general satisfaction. The people of the United States justly regard the construction of the Panama Canal as one of the great achievements in our national history. From the point of view of the constructing engineer, its completion, in advance of the estimated time and at less than the estimated cost, is a triumph for American engineering skill, for the Army engineer and for West Point training.

For his masterly ability as an organizer and administrator, highest praise is due to Colonel Goethals, and any reward which Congress or the President may see fit to confer on him will be well deserved; but the mechanical construction of the Panama Canal differs from other engineering feats only in size. The work of the Sanitary Department under Colonel Gorgas has not only been the greatest task of sanitation that has ever been undertaken, but it is also unique and epoch-making. For the first time in human history a region which, since the earliest traditions of civilization, has been regarded as a plague spot in which it was impossible for civilized man to live and work, has been converted into a place fitted for enjoyable habitation and labor, with a death-rate below that of the most modern cities. Such an achievement is not only of the most vital importance in making possible the construction of the canal, but it also has a broader and a far greater significance. It is a practical demonstration on a large scale of the possibilities of preventive medicine and of the application of scientific discoveries of the past fifty years in the prevention of disease.

While the general public will most readily grasp the importance of this work on account of its humanitarian aspect, the world of business has been convinced, as never before, of the practical commercial value of modern sanitation. Regions of the earth which have heretofore been closed to civilized man are, through Colonel Gorgas' work, made as habitable as any portion of our own country. Any section of the earth can now be developed, provided the cost of proper sanitation is provided. And in view of the results the cost is not prohibitive, but is a sound financial investment. Municipal and community health can be bought like any other commodity, and the responsibility for a high death-rate rests directly on these in authority. The public can fix its own death-rate by the amount it is willing to spend. These are new discoveries for civilization. Colonel Gorgas has worked them out to a positive demonstration. No matter what the future may have in store, civilized man can never recede to his old position of fatalism, résignation or indifference to the ravages of epidemic disease.

While Colonel Gorgas' work as canal commissioner and head of the Department of Sanitation has, perhaps, attracted more public attention than any other of his achievements. his long experience as a sanitarian, his noteworthy work in cleaning up Havana, his response to the request for his experience and advice at Guayaquil and in South Africa all furnish corroborative evidence, if any were needed, of his fitness for the high office to which President Wilson has appointed him. Graduating from medical college in 1879, and entering the Army Medical Corps in 1885, nearly his entire professional life has been passed in the government service. In 1903 he was promoted to the rank of colonel by special act of Congress, in recognition of his distinguished services. It is characteristic of the man and of the profession which Colonel Gorgas represents so well, that no reward in the form of great wealth will be his, nor would it be considered or accepted. The promotion which is his by right of seniority and which he has doubly earned by achievement, the holding for a few years of the position as Surgeon-General until the time for his retirement comes, the quiet and peaceful years of rest which he has so well earned, the satisfaction of work well done for the good of humanity—these are the modest rewards which will be bestowed on Colonel Gorgas, and they are the only rewards which would be worthy of the man, of his profession and of his monumental work.

FEVER AND DRUGS

Medical literature cannot be said to lack a liberal quota of contributions relating to fever. The theories and facts contributed to this subject might be presented in an almost endless array; yet there cannot be said to exist to-day a consensus of opinion as to the underlying mechanism, the factors which facilitate and maintain the existence of prolonged rise of temperature. Much of what has been written in the past about heat centers and temperature regulation is so vague and indefinite that, in not furnishing a guide for rational procedure in practice, it fails to serve the best purpose of hypothetic generalizations. For this reason it seems desirable to rehearse at some length the theory of fever and its treatment which was outlined by the Viennese pharmacologist H. H. Meyer at the last meeting of the German Congress for Internal Medicine.[1]

Owing to the fact that the production of heat in the body involves a chemical mechanism, whereas the dissipation of heat is accomplished by physical processes, and inasmuch as these two sets of phenomena manifest themselves at quite different places in the body, obviously some device must exist for the adjustment to each other of these two somewhat antagonistic processes. Precisely how the regulation of body temperature is accomplished with the nicety that prevails in the mammalian organism is a problem that has long called for elucidation. Admittedly, heat is lost from the body by the cooperation of a number of agencies that are well appreciated. The varying vascularity of the skin, the participation of the sweat-glands, etc., are features too familiar to call for detailed reference. It is not enough, however, to say that temperature regularity is maintained by variations either in heat dissipation or in production alone. To cite a single illustration, chemical reactions (which lead to heat production in the laboratory) are facilitated by heat and retarded by lowering temperatures; yet in the body, on the contrary, lowered temperature actually leads to an augmented heat production. Such considerations strengthen the conviction that there must be one or more central regulatory stations which effect a constancy of body temperature, despite the alterations in the discharge or liberation of heat which may arise in the individual seats of these responses.

That the central thermoregulator is located in the brain now seems undeniable; for when this organ is severed from the rest of the body a regulation no longer exists, and body temperature becomes adjusted to the environmental temperature, precisely as in the lower animals. Admitting the existence of central thermoregulatory devices, it becomes more than likely that every persistent alteration in body temperature, such as the rise in fevers or the fall in acute collapse, is connected with a change in the condition of the central regulatory mechanism.

Meyer postulates the existence of two groups of heat-regulating centers—the one thermogenic, leading to a conservation or production of heat in the body; the other thermolytic, facilitating heat dissipation and reduction of temperature. Both centers can be excited reflexly from the periphery, and they can also be inhibited. The conceptions here evolved are by no means new; but the evidence for the double regulatory device is growing from year to year. Barbour has actually succeeded in demonstrating that regulation may even be brought about by the effect of changing temperature directly at the centers in the corpus striatum. The local application of heat there is attended by a fall in body temperature, and conversely. According to Meyer, fever is the expression or consequence of an exaggerated excitability or irritability of the thermogenic center. When this arises it is not unlikely that the antagonistic cooling center is correspondingly inhibited, that is, rendered less susceptible to warmth. The thermogenic mechanism of control is believed to be a part of the sympathetic nervous system, in harmony with the fact that this system is known to be stimulated in conditions of hyperthyroidism, for example, in which tendencies to rise in temperature are not at all unusual. The conjecture likewise arises that the thermolytic mechanism is a part of the autonomic nervous system; for drugs such as picrotoxin, veratrin and digitalin, which undoubtedly stimulate autonomic centers like that of the vagus, occasion a fall in temperature.

---

[1] Meyer, H. H.: Theorie des Fiebers und seine Behandlung, Referat., Verhandl. d. deutsch. Kong. f. inn. Med., 1913, xxx, 15.

Any factor, whether physiologic or pharmacologic, which affects the irritability of these regulatory centers, can alter the level at which the temperature regulation of the body is maintained. If the susceptibility of the thermogenic center be increased or depressed, a sustained rise or fall of body temperature correspondingly ensues; and similar conclusions apply to alterations in the antagonistic centers. It is interesting to apply the reasoning to the conditions of practice. In deficiency of thyroid or hypophyseal functioning a tendency to subnormal temperature arises, a sign perhaps that with the lack of the glandular secretion the irritability of the thermogenic center is lowered. In fevers, on the contrary, the heating center is hyperexcitable, the cooling center depressed. Like all other overworked nervous centers, those related to the temperature regulation are fatigued more easily when in a state of overstimulation. Hence it is that the febrile person may experience a fall of temperature below his febrile normal after a cold bath, whereas the person in health responds to the cooling stimulus by prompt adjustment to the normal level. Greater interest centers in the interpretation of the action of antipyretic drugs in the light of the present hypothesis. Some of them, like quinin, antipyrin, acetanilid, etc., may be regarded as mild narcotics for the excited thermogenic center. Undoubtedly they also increase the loss of heat in diverse ways; but this would always be compensated by a renewed effort of the body to adjust to the febrile temperature norm, were not the heat center depressed at the same time by the antipyretic. The relation of drugs to the cooling centers is not so clear, but it seems probable according to Meyer that aconitin and veratrin act antipyretically by stimulating, that is, increasing, the susceptibility of the cooling centers. Whatever may be the final fate of the foregoing formulation of the relation of drugs to febrile temperatures, it can only be helpful to have some intelligible basis for therapeutic procedure, even if it be in part merely a temporary undemonstrated hypothetic expedient.

WHAT BECOMES OF THE PROTEIN DIGESTION PRODUCTS?

The study of the phenomena of nutrition is making rapid progress nowadays. So far as the rôle of the proteins is concerned, attention has become centered in the amino-acids as the fundamental food fragments with which all theories of nutrition must now be concerned.[1] So long as it was still assumed that the proteins are absorbed in a form relatively like the original foodstuff — for example, as proteoses or complex polypeptids — the theory of their subsequent metabolism had to be framed somewhat differently from that suggested by the conclusions of the most recent writers who assume that a more complete disintegration takes place in the digestive tract. To say that we absorb our protein intake in the form of amino-acids is, however, a long way from explaining the subsequent stages by which the ingested nitrogen becomes a part of the tissues.

The latest studies of Van Slyke and Meyer[2] of the Rockefeller Institute for Medical Research make it clear that absorbed amino-acids rapidly disappear from the blood as it circulates through the tissues. This disappearance from the circulation seems to be the result neither of the destruction of the amino-acids nor of their synthesis, nor yet of chemical incorporation into the cell proteins. They are somehow merely taken up by the tissues without undergoing any immediate change. In the case of the muscles, for example, a fairly definite saturation point exists, which appears to set the limit to the amount of amino-acids that can be absorbed. Van Slyke and Meyer have expressed the situation by saying that the amino-acids of the blood appear to be in equilibrium with those of the tissues — a condition which would account for many observed phenomena, such as any transfer of amino-acids which may occur from organ to organ, or from maternal organs to fetus.

It is unlikely, we are told, that the process by which the amino-acids — the real nitrogenous pabulum of the organism — are taken up and held by the tissues is wholly osmotic. Probably other factors, such as mechanical adsorption or the formation of loose molecular compounds between the amino-acids and the tissues, play a part. In any event the amino-acids do not remain long unaltered in the body, but disappear more rapidly from the liver than from any other organ to which they find their way. During the period, for example, required by the liver to rid itself entirely of absorbed amino-acids their concentration in the muscles suffers no appreciable fall; nor are the other organs — the kidneys, intestines, pancreas or spleen — markedly depleted. The long-defended dominance of the liver in the destructive metabolism of proteins is thus upheld by a new kind of evidence gained from a new point of view. While the muscles retain their quota of absorbed amino-acid tenaciously, the liver is pictured by Van Slyke and Meyer as continually desaturating itself by metabolizing the amino-acids which it has absorbed, and consequently maintaining indefinitely its power to continue to remove them from the circulation, so long as they do not enter it faster than the liver can degrade them. When the amino-acids reach the circulation too rapidly, or when the liver is pathologically degenerated, the familiar safety-valves of the body act. The kidneys now assist in removing the accumulated amino-acids by excreting them unchanged, precisely as an excess of circulating sugar is excreted in hyperglycemia. Finally, when the above-named agencies for preventing undue accumulation of protein digestion products are overtaxed, death may result.

---

[1] In What Form are Protein Digestion Products Absorbed? editorial, THE JOURNAL A. M. A., Dec. 20, 1913, p. 2245.

[2] Van Slyke, D. D., and Meyer, G. M.: The Fate of Protein Digestion Products in the Body: III, The Absorption of Amino-Acids from the Blood by the Tissues, Jour. Biol. Chem., 1913, xvi, 197; IV, The Locus of Chemical Transformation of Absorbed Amino-Acids, ibid., p. 213; V, The Effects of Feeding and Fasting on the Amino-Acid Content of the Tissues, ibid., p. 231.

These are new physiologic pictures in which the amino-acids are represented serving as a reserve supply of energy, like glycogen, or as a reserve of tissue-building material. They must soon become more familiar even to the busy practitioner; for they furnish a clearer and more promising outlook than could be gained in the hazy uncertainty which has so long surrounded the progress of digested protein through the organism.

Current Comment

THE TOXICITY OF EXPIRED AIR

The question whether or not expired air contains substances of unknown composition that have toxic action when introduced into the body by rebreathing or other means has been the subject of numerous investigations. The subject is of some theoretical but of greater practical interest in ventilation. From time to time positive findings have been reported, only to be challenged and denied by other investigators using the same methods more carefully controlled, the net result of all this work pointing to the conclusion that such toxic substances either are not present or are so greatly diluted that they play no rôle in ventilation. This left ventilation engineers and practical hygienists to deal with the temperature, the humidity, the carbon dioxid and unpleasant but non-toxic odors of the expired air. The old question took a new turn in 1911, when Rosenau and Amoss[1] reported their anaphylactic experiments with condensed exhalations from human beings. The experiments were positive, the guinea-pigs being sensitized by injections of the liquid condensed from the expired air, and the conclusion was drawn that the expired air contains a volatile protein or proteins of unknown composition. It does not follow from the work of Rosenau and Amoss that this protein is toxic or that it can be absorbed from the respiratory tract of the same species or different species. Recently the experiments of Rosenau and Amoss have been repeated with more careful controls by Weisman[2] at Columbia University. This investigator could not confirm Rosenau and Amoss on any point. Weisman's guinea-pigs were not sensitized by the isotonic condensation liquid from the human breath, nor did this liquid produce any toxic effect whatever in the guinea-pig even when injected in large doses. The work of Weisman appears to be carefully controlled, but it will probably not close this interesting chapter of respiration physiology.

FEEBLE-MINDEDNESS AS A CONSTITUTIONAL ANOMALY

The current emphasis on the rôle played by heredity in determining the make-up and functioning of the normal person has again brought into prominence the idea of constitutional defects as important factors in various manifestations of disease. The use of the term "constitutional" in relation to abnormalities of the organism is intended to contrast them with localized defects. It refers to a perverted behavior which pervades many, if not all, of the organs of the body instead of being limited to some definite region or isolated tissue. So long as the older type of pathologic anatomy was the dominant feature in the interpretation of diseased states it seemed almost inevitable to attempt to correlate each perversion of health with some specific, localized anatomic region—in other words, to find the definite seat of each disease. Of late, however, the still somewhat vague yet suggestive conception of constitutional defects is coming into vogue. The various so-called "diatheses" are gaining consideration as an expression of something more than an indefinable attribute of disease. Constitutional anomalies are thus becoming contrasted with localized defects. As expressed by a recent writer, the conception of constitutional anomaly "stands out as a minus variation from a normal standard and is characterized by the two significant marks of (more or less) generality and of inheritability." Dr. Amos W. Peters of the Training School at Vineland, N. J., has contended[3] that feeble-mindedness in general and from the point of view of its pathologic analysis should be regarded as a constitutional anomaly of the individual, which he has either inherited or acquired. As he points out, according to this hypothesis feeble-mindedness is not an isolated psychologic or even an isolated brain phenomenon, but is constitutional, general and far-reaching throughout brain and body. The importance of this view lies primarily in the fact that it points to the necessity of investigating the problems of the feeble-minded in directions additional to the customary psychologic, psychiatric or anatomic paths of scientific attack. So far as the broader sociologic aspects of the situation are concerned, one of the chief considerations undoubtedly is the prevention of the increase in the number of the feeble-minded. Here the potent influences of heredity must be confronted; but so far as feeble-mindedness is in any way likely to find remedial agencies, it marks a step in the direction of progress to deal with the purely physiologic aspects of the unfortunate situation. Particularly so far as acquired feeble-mindedness is concerned, that is, feeble-mindedness which may not primarily be hereditary in its origin, the most hopeful prospect appears in the search for a physiologic basis of the constitutional anomaly. Perverted function not infrequently finds an expression in various defects of metabolism. Here, then, is a possible land of promise for future research. Certain preliminary results, such as indications of abnormalities in the calcium metabolism of defectives of the Mongolian type already reported,[2] represent beginnings in this attempt to develop a physiologic pathology of the feeble-minded.

SUBSEQUENT HISTORY OF PATIENTS DISCHARGED FROM TUBERCULOSIS SANATORIUMS

In the excellent series of monographs published by the department of health of the city of New York is a report of an investigation begun in 1908 by the Council of Jewish Women to determine the status of patients discharged from tuberculosis sanatoriums. The information covered about a thousand patients discharged from a number of sanatoriums. The investigators were able to report on 554 of these, 100 of whom were dead. A difficulty that is encountered in all such investigations is the fact that a large number of those who have been discharged from the institution cannot be traced. The investigators debated whether such cases should be numbered largely among those dead or whether they are to be regarded as representative of the average and excluded from the calculation. The latter course is the one adopted, since it is shown that the number of deaths comes largely from the class discharged as improved or unimproved, while the investigation shows that those registered as "no trace" are drawn proportionately from all classes. The results show a steadily increasing number of deaths after discharge from the sanatorium, indicating a rather discouraging outlook for the sanatorium treatment. No satisfactory comparison can be made, however, because there are no data to show the outcome of similar cases without sanatorium treatment. What is really shown is that the sanatorium helps for a while and stimulates the patient to fight the disease better than he otherwise could. The social survey, however, shows what is yet but imperfectly recognized although repeatedly called to notice, namely, that the tuberculosis problem is a sociologic rather than a medical one. The majority of those discharged return to conditions which render the fight all but hopeless. Dark, insanitary tenements, fatiguing and poorly paid work, and lack of necessary care meet the discharged patient on his return from the sanatorium, and it is no wonder that the sanitary instructions of the institution are soon forgotten from sheer inability to apply them. To meet this difficulty, improvements in our methods are needed, both from a medical and from a sociologic point of view. The necessity of more sanatoriums so as to provide the patient with an opportunity to stay until better able to meet adverse conditions is evident. A more efficient medical supervision after the patient leaves the sanatorium is imperative. This can be promoted by the establishment of farm colonies or institutions where the patient can carry on his work under medical supervision. A sympathetic social control is needed that shall establish intimate confidential relations with the patient on entering the sanatorium, find out his home environment and provide for its improvement before his return, if necessary. This help should continue after his discharge and should provide for occasional reexamination.

RESEARCH IN MEDICAL MISSIONS

Wellman[1] says that it is not generally known that extensive use is made of our knowledge of tropical diseases by the medical missions in various parts of the world. He says also that these missions accomplish some of the best research in these diseases, in addition to teaching and applying scientific medicine among people who would otherwise be debarred from its benefits. In China it is said that there are over five hundred men and women engaged in the conduct of hospitals and dispensaries. The China Medical Mission Association meets triennially for the exchange of opinions and to make announcements of the results of research, and a bimonthly medical journal has been published for many years for the exchange of ideas in this field. A research committee has been formed and a large amount of valuable work has been done in the investigation of nematodes, trematodes, cestodes and the bacterial affections common to that part of the world, plague, cholera, typhus and other affections. Wellman says that more physicians and nurses are needed, and that to young men with the missionary spirit no more attractive field of endeavor could be found than that of China, Africa or India.

THE WISCONSIN MARRIAGE LAW DECLARED UNCONSTITUTIONAL

The apparent deadlock in Wisconsin over the amendment to the marriage law requiring a physician's certificate as a condition for a marriage license has been broken, for the present, at least, by the decision of the Milwaukee County Circuit Court that the law is unconstitutional and void. The matter was brought before the circuit court on an application for a writ of mandamus, directed against the county clerk, ordering him to issue a marriage license to an applicant without a health certificate. The court held that the amount of fee provided for the examinations as required by law was unreasonably low, and that the law was an undue interference with personal liberty. This decision, while only that of a circuit court, will act as a stay to the enforcement of the law until the higher courts have passed on the question. Probably no other topic has inspired so large an amount of newspaper comment in the past month. Wisconsin's experience should be a warning to state legislatures not to enact hasty and ill-considered laws on complex scientific subjects. The discussion of eugenics, race betterment and marriage regulation is productive of a large amount of good, but premature efforts to crystallize hastily formed opinions into laws can result only in confusion.

Medical News

GEORGIA

Georgia Surgeons to Visit Louisiana.—The members of the Georgia Surgeons' Club will be guests of the New Orleans profession, February 27 and 28; elaborate plans for entertainment have been made, and a number of interesting clinics have been arranged for the visiting surgeons.

New Officers.—Georgia Medical Society of Chatham County at Savannah, January 13: president, Dr. Justin L. Jackson; vice-president, Dr. Eugene R. Corson; secretary-treasurer, Dr. Victor H. Bassett, all of Savannah.——Georgia Surgeons' Club at Atlanta: president, Dr. Edward C. Davis, Atlanta; secretary-treasurer, Dr. H. Clay Willis, Rome.——Thomas County Medical Association at Thomasville, December 18: president, Dr. James N. Isler, Meigs; secretary-treasurer, Dr. Arthur D. Little, Thomasville.——Macon Medical Society, December 3: president, Dr. Thomas H. Hall; secretary-treasurer, Dr. R. H. Stovall.——Eleventh District Medical Society at Valdosta: president, Dr. Charles W. Roberts, Douglas; secretary, Dr. J. W. Simmons, Jr., Brunswick. St. Simon's Island was selected as the next place of meeting for the society.

ILLINOIS

New Officers.—St. Clair County Medical Society at East St. Louis, January 8: president, Dr. August F. Bechtold, New Athens; secretary, Dr. Buenaventura H. Portuondo, Belleville.

Chicago

Personal.—Dr. Charles J. Rowan has been appointed head of the department of surgery at the State University of Iowa, Iowa City, to succeed Dr. William Jepson, Sioux City, resigned. ——Lieut. Col. Jacob Frank and Majors Buell S. Rogers and Charles B. Walls, M. C., Ill. N. G., were appointed members of the Board of Examiners of Medical Officers.——Dr. Antonio Lagorio was guest of honor at a dinner given by the Italian Chamber of Commerce at Chicago, January 17.

INDIANA

Sanitarium Closed.—The Gilbert Memorial Sanitarium, Evansville, which was built about two years ago at a cost of $100,000 has been closed. About February 1 it will be converted into an apartment building.

Gift to University.—The State University has been given a tract of 160 acres in Texas by George T. Kerr, Indianapolis; the proceeds of the sale of this land will be used to furnish a ward in the new Robert W. Long Memorial Hospital. (Fox)

New Officers.—Hancock County at Greenfield, January 10: president, Dr. Paul E. Trees, Maxwell; secretary-treasurer, Dr. Joseph L. Allen, Greenfield.——Wayne County at Richmond, January 7: president, Dr. Charles E. McKee, Dublin; secretary, Dr. Arthur J. Whallon, Richmond.

Hospital Notes.—The first two units of the Indianapolis City Hospital will be ready for occupancy by February. They will have cost $300,000 and will accommodate 450 patients. ——The Robert W. Long Memorial Hospital, which will be completed February 1, will be used to accommodate free patients from all parts of the state. (Fox)

State Medical Board Reorganizes.—The State Board of Medical Registration and Examination met in Indianapolis, January 13, for reorganization; Dr. James M. Dinnen, Fort Wayne, was elected president; Dr. W. A. Spurgeon, Muncie, vice-president; Dr. William T. Gott, Crawfordsville, was reelected secretary, and Dr. Moses S. Canfield, Frankfort, reelected treasurer.

Personal.—Dr. Homer J. Hall, Franklin, was operated on January 9, at the Methodist Hospital, Indianapolis, for gall-stones.——Dr. Albert G. Coyner has been reappointed secretary of the board of health of Kendallville, where he has had twenty-three years of continuous service.——Dr. Edgar C. Loehr has entered on his second term as mayor of Noblesville.——Dr. Nettie B. Powell has been elected health officer of Marion.——Dr. Augustus L. Marshall has been appointed superintendent of the Indianapolis Municipal Dispensary, vice Dr. David W. Fosler, resigned.——Dr. William W. Vinnedge, Lafayette, was seriously injured recently in a collision between his buggy and a motor car.——Dr. John E. Hoover, Indianapolis, who was operated on recently for mastoiditis, is making good progress toward recovery.——Dr. Frank C. Robinson, Martinsville, is spending the winter in California and Florida.

IOWA

Site for Epileptic Colony Purchased.—The State Board of Control has purchased for $200,000 the Flynn farm as a site for the State Epileptic Colony. It is three miles west of the city limits of Des Moines, and contains 1,080 acres, and buildings valued at $60,000.

Hospital Board Officers Elected.—At the annual meeting of the medical board of the Jenny Edmundson Memorial Hospital at Council Bluffs, January 5, the following officers were elected: president, Dr. Alfred P. Hanchett; secretary, Dr. Mary L. Tinley; members of the executive committee: Drs. Donald Macrae, Louis L. Henninger and Earl Bellinger.

Personal.—Dr. Robert I. Rizer and family, Clinton, sailed for Europe January 8.——Dr. George Hofstetter, Clinton, who was operated on recently in Rochester, Minn., is reported to be making favorable progress toward recovery.——Dr. H. H. McCrea, Boone, has been unanimously elected president of the Boone Country Club.——Dr. Paul R. Burroughs, Allison, fractured his arm at the wrist, December 27, while cranking his motor car.

New Officers.—Ringgold County Medical Society at Mount Ayr, January 8: president, Dr. James H. Goad, Ellston; secretary, Dr. Samuel Bailey, Mount Ayr, both reelected.——Montgomery County Medical Society at Red Oak, December 31: president, Dr. Louis A. Thomas; secretary-treasurer, Dr. Velura E. Powell, both of Red Oak.——O'Brien County Medical Society at Sheldon, December 29: president, Dr. William C. Hand; secretary, Dr. J. B. Sherbon, both of Hartley, both reelected.——Henry County Medical Society: president, Dr. D. S. McConnaughey, Wayland.——Muscatine County Medical Society at Muscatine, December 30: president, Dr. Edward K. Tyler; secretary-treasurer, Dr. William H. Johnson, both of Muscatine and both reelected.——Lee County Medical Society at Fort Madison, December 30: president, Dr. John R. Walker, Fort Madison; secretary-treasurer, Dr. Ernest G. Wollenweber, Keokuk (reelected).

KANSAS

New Officers.—Douglas County Medical Society at Lawrence, January 13: president, Dr. Harry L. Chambers; secretary, Dr. E. James Blair, both of Lawrence.——Franklin County Medical Society at Ottawa, December 30: president, Dr. Willis L. Jacobus; secretary-treasurer, Dr. James P. Blunk, both of Ottawa.——Reno County Medical Society at Hutchinson, January 2: president, Dr. Charles L. McKittrick; secretary-treasurer, Dr. William F. Schoor, both of Hutchinson.——Sedgwick County Medical Society at Wichita, December 16: president, Dr. Lloyd P. Warren; secretary-treasurer, Dr. Frank S. Whitman, both of Wichita.——Cowley County Medical Society at Arkansas City, December 11: president, Dr. Walter P. Guy, Winfield; secretary, Dr. B. C. Geeslin, Arkansas City.

Personal.—Dr. John C. Cornell has resigned as city physician of Parsons.——Dr. Charles F. Menninger, Topeka, who was operated on at Christ Hospital, January 9, for removal of gall-stones, is reported to be improving.——Dr. Charles H. Fortner, Coffeyville, while making a professional call, was attacked by an unknown assailant and seriously injured.—— Dr. Philip B. Matz, assistant surgeon at the Soldiers' Home at Leavenworth for several years, has resigned and will be pathologist for St. John's and in the Cushing Hospital in that city.——Dr. Benjamin F. Hawk, Harper, has been appointed superintendent of the Larned State Hospital for the Insane, which will be ready to receive patients by February 1.—— Drs. James W. May, Kansas City, and Roy B. Guild, Topeka, have been appointed members of the Cosmopolitan Health Commissioners, whose duty is to recommend to the legislature a plan for the reorganization of the public health service in Kansas City.

KENTUCKY

Tuberculosis District Formed.—The counties of Christian, Fayette and Henderson voted, on December 16, to form themselves into tuberculosis districts that they may be provided with sanatoriums for tuberculosis.

Conflict Against Trachoma.—Drs. J. F. Oakley, F. Kalb and C. Moore, U. S. P. H. S., have combined in a crusade against trachoma in Jefferson County. All the schools in the county will be visited and the pupils examined; and all the schools, orphanages and other institutions in the county will be included in the investigation.

Personal.—Dr. Joseph W. Fowler has been reelected superintendent of the Louisville City Hospital.——Dr. Basil M. Taylor, Greensburg, who has been ill for several months, has gone to Florida for the remainder of the winter.——Dr. John Q. Taylor, Paducah, has been appointed chief surgeon of the Illinois Central Hospital, and Dr. Frank Boyd assistant surgeon.——Dr. Will C. Strouther, Bowling Green, is ill with septicemia following an accidental gun-shot wound in the hand.——Dr. Grover S. Brzozowski has succeeded Dr. Charles H. Whitlatch as health officer of Louisville.——Dr. Walter R. Francis, Bowling Green, suffered the fracture of several ribs in a runaway accident, December 19.——Dr. Richard B. Gilbert has been appointed a member of the board of trustees of the Louisville Tuberculosis Hospital.

NEW JERSEY

Tuberculosis Hospital to Open.—The Morris County Sanatorium, Morristown, will be formally opened February 1. The building will accommodate thirty patients.

Asks Home for Defectives.—Superintendent Kalleen, of the State Home for Boys, has asked an appropriation of $40,000 for a special home for defectives. In an examination of forty-eight boys taken from the inmates of the home, the report showed that eighteen were decided cases of feeblemindedness. Two had characteristics of insanity and thirteen were border-line cases.

New Officers.—Atlantic County Medical Society at Atlantic City, January 9: president, Dr. Walt P. Conaway; secretary, Dr. Edward Guion (reelected), both of Atlantic City.——Newark Medical Library Association, December 30: president, Dr. Edward J. Ill; secretary-treasurer, Dr. Frank W. Pinneo.——Mercer County Medical Society at Trenton: president, Dr. Frank G. Scammell; secretary, Dr. Horace D. Bellis, both of Trenton.

Personal.—Dr. Harry F. Bushey, Camden, has been sworn in as one of the coroners of Camden County.——Dr. Herman C. H. Herold has been reelected president of the Newark Board of Health, for the nineteenth term.——A dinner was given by the physicians of Elizabeth and vicinity to Dr. Victor Mravlag, mayor of Elizabeth, on the fortieth anniversary of his beginning work as a practitioner. A gold watch, engraved with his monogram, was presented to Dr. Mravlag.

NEW YORK

New Officers.—Cattaraugus County Medical Society at Salamanca, January 9: president, Dr. Herman W. Johnson, Gowanda; secretary-treasurer, Dr. Herman H. Ashley, Machias.——Yates County Medical Society at Penn Yan, January 6: president, Dr. John A. Conley, Penn Yan; secretary, Dr. George E. Welker, Dresden.

New Tuberculosis Sanatoriums.—The Board of Supervisors of Westchester County has voted to purchase 225 acres of land at North Castle for $33,500 as a site for a county tuberculosis hospital. The new buildings as planned will cost $200,000. This makes twenty counties in this state which have erected or planned to erect similar hospitals.——Work on the Onondaga County Tuberculosis Sanatorium on the Hopper's Glen site has begun. The plans provide for an administration building, to which, eventually, two wings will be added. The ward building is to be used for advanced cases of tuberculosis, while the administration building will be used for incipient cases.

New York City

Trichinosis a Reportable Disease.—At the meeting of the Board of Health Dec. 9, 1913, a resolution was adopted requiring all physicians to report cases of human trichinosis to the Department of Health.

Popular Health Lectures.—A series of lectures is to be given by the Medical Society of the County of New York Public Health Education Committee at the New York Academy of Medicine on alternate Tuesday evenings and Thursday afternoons from January 8 to March 5. This course of lectures is given in cooperation with the Public Health Education Committee of the American Medical Association.

New Officers.—Italian Medical Society, December 26: president, Dr. Felippo Cassola; secretary, Dr. John Corcia; corresponding secretary, Dr. Francis A. Auleta. It was decided to hold monthly meetings of the society to encourage Italian medical men of talent and ability to raise their professional standards, and to discuss ways and means of handling the problems which confront Italian physicians, such as the questions of midwives and lodge practice.

Personal.—Dr. Herman M. Biggs has been appointed State Commissioner of Health, and his name sent to the Senate for approval and confirmation.——Dr. William H. Knipe has been appointed visiting physician to the Gouveneur Hospital, Dr. George L. Brodhead visiting obstetrician to the Harlem Hospital, and Drs. Thomas H. Cherry and Arthur Stein have been made assistant visiting obstetricians to the Harlem Hospital.——Dr. Sigismund S. Goldwater, superintendent of Mount Sinai Hospital, on January 20, was appointed health commissioner by Mayor Mitchell.

New Cancer Laboratory Ready.—The Cancer Research Laboratory, which was the gift of the late George Crocker to Columbia University, is complete, and Dr. Francis C. Wood and his assistants are moving into the building. While the structure is meant only as a temporary housing for the laboratory, no pains have been spared in making it meet every present need. The laboratory is on the site purchased several years ago for the College of Physicians and Surgeons, but which has not been used for that purpose since the affiliation between Columbia and the Presbyterian Hospital.

Report of New York Academy of Medicine.—The annual report of the trustees of the New York Academy of Medicine shows that during the past year the trust funds have been increased by a bequest of $1,000 from the estate of the late Dr. James P. Tuttle which is to be used for the purchase of books relating to the gastro-intestinal tract. The principal of the library fund has been increased by $226 from the sale of triplicates, the endowment fund by $1,425 from admission fees, and the general permanent fund by $150. The academy extension fund has now reached the sum of $81,460. The total amount pledged to date is $125,225.

For Welfare of City Employees.—A plan is under consideration for the organization of welfare work among the employees of the Department of Health. The plan embraces the investigation of all absences over forty-eight hours, the keeping of records of the physical condition of all employees, the provision and supervision of a suitable retiring room for women and of a suitable lunch room, the establishment of an open-air garden for the use of employees during lunch hours, the organization of a vacation camp for women, and the delivery of lectures on personal hygiene. A committee has been appointed to perfect and carry out the plans.

Reform Suggested in City Hospitals.—At the meeting of the board of estimate on January 16 the report of two years' investigations of the city hospitals was submitted. This was only one of a series of reports on this subject and contained criticism of the manner of handling children in these institutions. It is claimed that there are many defects in the present system which expose the children to infection. The committee condemned the Randall's Island site of the old Children's Hospital as inaccessible and recommends a point just south of the City Home as the proper site for the new long-term children's hospital. This proposed institution should be planned to accommodate 1,000 children ultimately. Here the committee proposes to centralize the children's cases now distributed through the hospital system.

Distributing Hospital Funds on New Basis.—The Hospital Saturday and Sunday Association which has hitherto distributed cash among those hospitals which announced that they would receive charity cases, will hereafter take into consideration the cost of all free treatments and will allow up to $3 a day for surgical cases, but only 75 cents a day for convalescents and incurables. The association will strike from the roll of beneficiaries all hospitals marked "Grade C" on the records of the State Board of Charities. Such institutions will receive this year only 50 per cent. of their former allowance, and next year will be dropped altogther. It has also been decided that no hospital shall be admitted to membership unless it has a minimum of thirty-five beds and has given at least 5,000 days of free service a year for three years preceding the date of its admission.

NORTH CAROLINA

State Hospital Addition Nearly Ready.—Work on the addition to the Morganton State Hospital for the Insane is being rapidly pushed, and the building will be ready to receive patients by early summer.

New Hospital.—The Corcoran Hotel building, Durham, has been remodeled and will open in a short time as the Mercy Hospital, under the charge of Dr. Claude A. Adams and a select staff of physicians of Durham.

Personal.—Dr. Paul O. Schallert, Winston-Salem, was seriously injured in an automobile accident recently.——Dr. Harry Q. Alexander, Matthews, has been reelected president, and Dr. James M. Templeton, Cary, vice-president, of the North Carolina Farmers' Union.

New Vital Statistics Law.—The North Carolina Board of Health has secured the services of Dr. James R. Gordon, Jamestown, state senator from Guilford County, to visit all sections of the state, all medical societies, and all others concerned with the new vital statistics law, advising and instructing them as to its provisions, and to urge their hearty cooperation in securing effective registration.

New Officers.—Iredell-Alexander Counties Medical Society at Statesville, January 5: president, Dr. F. A. Carpenter, Mooresville; secretary, Dr. John E. McLaughlin, Statesville.——Wake County Medical Society at Raleigh: president, Dr. Jessie A. Strickland, Zebulon; secretary, Dr. William C. Horton, Raleigh.——Wilson County Medical Society at Wilson: president, Dr. Albert F. Williams; secretary-treasurer, Dr. Michael M. Saliba, both of Wilson.

OHIO

Dayton Physicians to Replace Flood-Damaged Books.—The Montgomery County Medical Society at its regular meeting at Dayton, January 2, voted that its annual appropriation for reference books for its library should be used this year to replace books lost in, or damaged by the floods of last spring.

Personal.—Dr. T. Addison McCann, Dayton, was reelected president, and Dr. Lee Humphrey, Malta, vice-president, of the State Medical Board at its annual meeting in Columbus.——Dr. William A. Dickey, Toledo, has been appointed surgeon of the police and fire departments.——Dr. H. L. Rockwood, Cleveland, has been appointed resident physician of the Warrensville Tuberculosis Sanatorium.——Dr. George P. Ikirt, East Liverpool, who has been seriously ill with pneumonia, is reported to be convalescent.——Dr. R. M. Manley, Cleveland, has returned from abroad.

New Officers.—Portage County Medical Society at Ravenna, January 8: president, Dr. Louis W. Prichard; secretary, Dr. Cyrus O. Jaster, both of Ravenna.——Clark County Medical Society at Springfield, January 12: president, Dr. James E. Studebaker.——Dayton Academy of Medicine, January 9: president, Dr. William H. Delscamp; secretary, Dr. Leo R. Courtright.——Coshocton County Medical Society at Coshocton, January 8: president, Dr. Thomas W. Lear; secretary, Dr. Jacob D. Lower, both of Coshocton.——Washington County Medical Society at Marietta, January 6: president, Dr. Stanford E. Edwards; secretary, Dr. Stephen A. Cunningham, both of Marietta.——Summit County Medical Society at Akron, seventy-third annual meeting January 6: president, Dr. David H. Morgan; secretary, Dr. Alexander S. McCormick (reelected), both of Akron.——Delaware County Medical Society at Delaware, January 2: president, Dr. Arthur H. Buck; secretary-treasurer, Dr. Wendell G. Hyatt, both of Delaware.

Cincinnati

New Officers.—Cincinnati Academy of Medicine, January 5: president, Dr. Allen B. Thrasher; secretary, Dr. Charles T. Souther.

Leipzig Professor At University.—Dr. Wolfgang Ostwald of the University of Leipzig is giving a series of lectures on colloid chemistry. The course is being given under the auspices of the Cincinnati section of the American Chemical Society and the Cincinnati Medical Research Society.

Association for the Welfare of the Blind.—The Cincinnati Association for the Welfare of the Blind has submitted its annual report for 1913. Much credit is due to Dr. Louis Stricker for his untiring energy and interest in the work of prevention among new-born infants. So far as is known, there has been absolutely no blindness during the past year resulting from ophthalmia neonatorum, due largely to the promptness with which cases have been reported for treatment. The work done in the workshop amounted to $14,598. Quite a number of blind men have been given employment in the shop, each receiving a wage of $6 per week.

OKLAHOMA

Hospital Notes.—The board of trustees of the Insane Hospital, Supply, has decided to erect a modern and fireproof hospital, which is to replace the building destroyed by fire in December last.——The Blackwell Hospital, Blackwell, was formally opened January 8.

Personal.—Dr. Walter Rendtorff, Anadarko, who has had charge of the Kiowa Agency school, has been promoted to a similar position in the Indian School, Carlisle, Pa.——Dr. Ernest L. Bagby, Fairfax, has assumed charge of the East Oklahoma Insane Hospital, Vinita.——Dr. Walter B. Reeves, Wapanucka, who was recently sued for malpractice, was completely vindicated, the court dismissing the case without submitting it to the jury.——Dr. Curtis R. Day, Oklahoma City, has been appointed dean of the medical school, vice Dr. William J. Jolly. (Watson)

New Officers.—Oklahoma County Medical Society at Oklahoma City, January 11: president, Dr. Millington Smith; secretary-treasurer, Dr. Frank B. Sorgatz, both of Oklahoma City.——Alfalfa County Medical Society at Cherokee, January 8: president, Dr. H. A. Lile, Aline; secretary-treasurer, Dr. Lloyd T. Lancaster, Cherokee.——Blaine County Medical Society at Watonga, January 8: president, Dr. James S. Barnett, Hitchcock; secretary-treasurer, C. Williams, Watonga.——Caddo County Medical Society at Anadarko, January 1: president, Dr. Benjamin D. Brown; secretary-treasurer, Dr. Chas. R. Hume, Anadarko.——Washita County Medical Society: president, Dr. Julius Farber, Cordell; secretary-treasurer, Dr. William Leverton, Cloud Chief.——Lincoln County Medical Society: president, Dr. Chas. M. Morgan, Chandler; secretary-treasurer, Dr. Frank B. Erwin, Wellston.

PENNSYLVANIA

New Officers.—Butler County Medical Society at Butler, January 14: president, Dr. Guy [illegible] tary, Dr. William Blaine Clark, both of [illegible] County Medical Society at Pittsburgh, January 13: president, Dr. John A. Hawkins; corresponding-secretary, Dr. Carey J. Vaux, both of Pittsburgh.——Elk County Medical Society: president, Dr. Stanley Barrett; secretary, Dr. Samuel G. Logan, Ridgeway.——Lancaster County Medical Society at Marietta, January 8: president, Dr. A. Z. Walters, Brownstown; secretary, Dr. Horace C. Kinzer, Lancaster.——Lycoming County Medical Society at Williamsport, January 9: president, Dr. Clarence E. Shaw; secretary, Dr. Robert F. Trainer, both of Williamsport.——York County Medical Society at York, January 8: president, J. N. Dinnick; secretary-reporter, Dr. Julius H. Comroe, York.——Northumberland County Medical Society at Sunbury, January 7: president, Dr. Charles A. Allison, Elysburg; secretary, Dr. Horatio W. Gass, Sunbury.——Fayette County Medical Society at Uniontown, January 6: president, Dr. Wilbur M. Lilley, Brownsville; secretary-treasurer, Dr. Joseph P. Ritenour, Uniontown.——Dauphin County Medical Society at Harrisburg, January 6: president, Dr. John F. Culp; secretary-treasurer, Dr. Frank D. Kilgore.——Ellwood City Medical Society, January 5: president, Dr. Charles Iseman; secretary, Dr. Boyd W. Shaffner.

Philadelphia

Mrs. Mitchell Dies.—Mrs. S. Weir Mitchell died from pneumonia, January 15, eleven days after the death of her husband.

Personals.—Dr. Francis Taylor, Police Surgeon, had his right fore-arm broken while cranking his automobile.——Dr. George Weinstein met with a similar accident during the past week.——Dr. M. Frazer Percival was elected roentgenologist to the Polyclinic Hospital to fill the vacancy caused by the death of Dr. Charles Lester Leonard.

Gift to Germantown Hospital.—At a meeting of the Board of Managers of the Germantown Hospital and Dispensary, it was announced that a nurses' home fully equipped would be given to the hospital by Mrs. William G. Warden, in memory of her husband. The cost of the building and equipment will be $60,000. This gift makes it possible for the hospital to accept the offer of Miss Gertrude Homer to build a maternity ward in memory of her father, Thomas B. Homer.

To Improve Blockley.—For the improvement and enlargement of the facilities of the Philadelphia General Hospital, the committee on the reorganization of that institution urged the appropriation by councils of $50,000 for the immediate employment of a competent hospital architect to prepare plans for the reconstruction work. The committee consists of Drs. Charles K. Mills, C. H. Frazier, M. B. Hartzell, H. B. Allyn, W. M. L. Coplin, E. H. Siter, Henry Sykes, Joseph Sailer, D. H. Weisenburg, H. C. Carpenter, J. B. Carnett and David Riesman.

Hamilton Mabie on Tokyo Hospital.—A mass meeting was held at Holy Trinity Church, Walnut and Nineteenth Streets, January 19, in the interest of St. Luke's Hospital, Tokyo, when Rt. Rev. A. L. Lloyd, D.D., and Mr. Hamilton Mabie spoke. They have recently returned from Japan, and have much to tell of medical and surgical work accomplished by Dr. Tuesler and Dr. Bliss who are in charge. The Japanese government recognizes the ability of these physicians, and has promised aid in building a new and much-needed hospital in Tokyo to be under their direction.

Annual Elections.—Philadelphia Clincal Association: president, Dr. Samuel M. Wilson; secretary, Howard D. Geisler.——Northwest (Germantown) Branch of the Philadelphia County Medical Society: chairman, Dr. H. B. Wilmer; clerk, Dr. C. C. Watt, Jr.——South Branch of the Philadelphia County Medical Society: president, Dr. Paul B. Cassidy; secretary, Dr. Joseph M. Endres.——Pathological Society of Philadelphia: president, Dr. D. J. McCarthy; secretary-treasurer, Dr. W. H. P. Pepper.——Samaritan Hospital Medical Society has chosen these: president, Dr. Edward K. Mitchell; secretary-treasurer, Dr. Charles T. Russell, Jr.——Medical Club of Philadelphia, January 16: president, Dr. Samuel D. Risley; secretary, Dr. William S. Wray. Resolutions were adopted deploring the great loss to the Medical Club in the death of Dr. S. Weir Mitchell.

WASHINGTON

New Officers.—Spokane County Medical Society at Spokane, January 8: president, Dr. John H. O'Shea; corresponding-secretary, Dr. Clarence A. Veasey, both of Spokane.——Pierce County Medical Association at Tacoma, January 6: president, Dr. William N. Kellar; secretary, Dr. Edward O. Sutton, both of Tacoma.

WISCONSIN

State Board Elects.—The State Board of Health, at its meeting held January 9, elected Dr. William F. Whyte, Watertown, president, and Dr. Edward S. Hayes, Eau Claire, vice-president; Dr. Cornelius A. Harper, Madison, is continued as secretary.

New Officers.—Milwaukee Medical Society, January 13: president, Dr. Robert C. Brown; secretary, Dr. Oscar Lotz.——Manitowoc County Medical Society at Manitowoc, January 7: president, Dr. William G. Kemper; secretary-treasurer, Dr. William E. Donahue, both of Manitowoc.

Personal.—Dr. John M. Beffel, Milwaukee, has been reappointed a member of the State Board of Medical Examiners.——Dr. Fay T. Clark, Waupun, has been appointed a member of the State Board of Medical Examiners to succeed Dr. Milton Rice, resigned.——Dr. Alexander Montgomery, Eau Claire, was severely burned while attempting to put out a fire in his house, January 7.

Amount Paid Out Under the Compensation Law.—In the two years during which the workmen's compensation law has been in operation the employers of labor have paid as indemnity to injured persons and their dependents in case of death, the sum of $396,354. This amount does not include the amount paid under the medical relief provision of the law, which it is estimated will equal 50 per cent. of the amount paid as indemnity.

GENERAL

Appropriation for Breakwater.—The Secretary of the Treasury has sent the House of Representatives, on January 15, a supplemental estimate of $40,000 for a breakwater for the United States Marine Hospital, Chicago.

Insurance Directors' Meeting.—The medical section of the American Life Company will hold its semi-annual session at French Lick Springs, Ind., March 4-6; Dr. J. Allison Hodges, Richmond, Va., is chairman of the program committee.

Gynecologists to Meet.—The American Gynecological Society announces its annual meeting, to be held at Boston, May 19 to 21. Prof. Dr. W. Nagle, Berlin, will deliver an address on "Operative Treatment of Prolapse of the Vagina, and Results."

Edward N. Bibbs Memorial Prize Fund.—The income of this fund, which amounts to about $500, is used in aiding investigators into the cause and treatment of diseases of the kidney. The recipient of the fund is chosen annually. The committee will select the worker for 1914 about the first of February. For information write to the Committee of the Edward N. Gibbs Memorial Prize Fund, 17 West Forty-Third Street, New York City.

Small-Pox in the Navy.—Thirty-four new cases of small-pox have developed at the Guantanamo naval station among sailors exposed on the *Ohio*. The station at Guantanamo has been quarantined, and the Atlantic fleet which was scheduled to start south, January 11, making its base at Guantanamo, will remain at Culebra, Porto Rico, until the end of January. The third death among the men exposed on the *Ohio* occurred at Charleston, S. C., January 7. Nine of the cases at Guantanamo are said to be severe.

Bequests and Donations.—The following bequests and donations have recently been announced:

Hebrew Orphan Asylum, United Hebrew Charities and Mt. Sinai Hospital, New York City, $2,500 each, by the will of William Scholle.

Presbyterian Hospital, New York City, residuary legatee of the estate of Miss Elizabeth Thompson, for $350,000.

Lenox (Mass.) Library, $2,500 by the will of Richard C. Greenleaf.

New England Hospital for Women and Children, Boston; Women's Medical College of Pennsylvania, Philadelphia; Corning (New York) Hospital, each $1,000 by the will of Alfred Jones, Boston.

Chicago Home for the Friendless; Lying-In Hospital; Presbyterian Hospital; St. Luke's Hospital, and Passavant Hospital, equal shares of the residuary estate of Thomas S. Kirkwood which amounts to about $415,000.

Maimonides Kosher Hospital, Chicago, donation of $5,000 from Abraham Slimmer, Dubuque, Iowa.

National Jewish Hospital for Consumptives, Denver, a donation of $10,000 from David May, St. Louis.

Kenosha (Wisconsin) Hospital, 5 per cent. of the estate of Max Rosenbloom, about $1,250.

Orthopedic Hospital and Society for the Relief of the Ruptured and Crippled, New York City, each $7,500 by the will of Marion de Forest Clark.

Children's Aid Society, St. John's Guild, United Hebrew Charities, Hebrew Orphanage, New York City, each $7,304, by the will of Major Ovan Tailof.

St. Luke's Hospital, New York City, $7,500 by the will of Henry M. Sands.

FOREIGN

Other Deaths in the Profession Abroad.—Dr. J. De Boeck, professor of psychiatry and medical jurisprudence at the University of Brussels.——Dr. A. Cugini, professor of medical jurisprudence at the University of Parma.——Dr. Zambaco Pasha of Constantinople died recently at Cairo at an advanced age. He had just added to his numerous works on leprosy another entitled "La lèpre dans l'Egypte actuelle." He had also recently published a work on eunuchs in the past and present.

CANADA

New Officers.—A new Catholic medical society has been organized in Montreal, of which Dr. Israel J. Desroches has been elected president.

Grenfell Institute Debt Free.—The Seamen's Institute, St. John's, Newfoundland, founded by Dr. Wilfred T. Grenfell, the Labrador medical missionary, is free from debt, and began the New Year without incumbrance.

The New University.—Dr. F. F. Wesbrook, president of the new University of British Columbia, is in the East looking for material to organize his staff. In March it is expected that a start will be made on the new university buildings to be erected in Vancouver, toward which the government of British Columbia has granted 250 acres of land. By the autumn of 1915 Dr. Wesbrook hopes that the university will be able to commence operations. In his quest Dr. Wesbrook has visited practically all the great universities of the United States and Canada.

Personals.—Dr. Rosaire Paquin has been appointed medical officer of health for Quebec City, in place of Dr. Laurent Catellier who has resigned, but will remain as consulting physician to the city. Dr. Joseph C. Gosselin has been appointed assistant to Dr. Paquin.——Dr. Evelyn J. Evatt, Winnipeg, professor of anatomy in the Manitoba Medical College, has accepted the position of professor of anatomy in Dublin University, formerly held by Dr. Geddes, who has been appointed professor of anatomy in McGill University, Montreal.——Dr. Edward V. Hogan, Halifax, N. S., has been appointed professor of surgery in the Halifax Medical College, Dr. John Stewart giving some additional lectures.

Hospital News.—To prevent multiple and proxy voting the staff of the Western Hospital, Toronto, is asking the Ontario government for special legislation to place this hospital on the same level as other hospitals in Ontario. In the present hospital act there is a provision giving donors of large sums of money a number of votes as multiples of $100. The medical staff wants "one man, one vote."——A new isolation hospital has been opened at St. Thomas, Ont. It consists of three cottages, two of which are completed; a third is to be built for small-pox patients.——Notre Dame Hospital, Montreal, is to have a new four-story addition, to cost $12,000.——A new building is to be erected for the Tuberculosis Sanatorium at Tranquille, B. C.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Jan. 10, 1914.

The Royal Commission on Venereal Diseases

At the last meeting of the Royal Commission on Venereal Diseases, Mr. J. E. Lane, senior surgeon of St. Mary's Hospital and of the London Lock Hospital and a member of the commission, gave evidence. In his opinion venereal diseases are attended by just as great a mortality as tuberculosis or cancer. He thinks that these diseases are somewhat less prevalent than they were twenty or thirty years ago, but it is difficult to speak with certainty as the statistics of certified deaths from syphilis do not give any idea of the prevalence of the disease. Although large subscriptions are given to the cause of combating other diseases, nothing is done for venereal diseases. Mr. Lane laid stress on the necessity for improved and free hospital treatment. He considered that every patient suffering from venereal disease should be entitled to gratuitous treatment and bacteriologic tests. On the subject of notification he had changed his opinion. Formerly he was in favor of reporting all cases to the sanitary authority, but he has now modified his view because he was convinced that notification would deter sufferers from seeking proper advice and would lead to increased resort to quack treatment. With regard to the education of public opinion as to venereal diseases, he said that in the first place every infected person should be instructed. It should be made compulsory for physicians to supply every patient suffering from a venereal disease with printed instructions as to the nature of the disease and the measures to be adopted in order to avoid spreading the disease to the public. Copies of such instructions should be supplied gratuitously to physicians. In colleges and universities and in all institutions in which there are a large number of employees courses of lectures on the dangers of venereal diseases should be given. It is also of great importance that the standard of knowledge of these diseases in the medical profession should be raised. In the past the teaching in the medical schools has been very inadequate, but steps are now being taken which should lead to improvement.

Dr. T. H. C. Stevenson, superintendent of statistics to the registrar-general of England, also gave evidence. He admitted that the statistics tabulated of death from syphilis did not afford any measure of the absolute amount of venereal disease, but they threw light on its relative amount, whether the comparison be historical, geographical or social. Taking the first, the curve of mortality from syphilis showed a large and rapid rise between 1850 and 1868, followed by a period of fairly sustained elevation till about 1886. This was succeeded by ten years of rapid fall. After 1896 the fall continued, but was less rapid. Dr. Stevenson thought that the fall in the last thirty years represented a genuine decrease in the mortality from the disease. Contemporaneously there was a great fall in the prevalence of the disease in the army and navy. As to social prevalence, the disease was most frequent in the highest and in the lowest classes.

A Hospital for the Middle Class

In London the poor are well provided with hospitals at which they are treated gratuitously, and the rich can command, either in their own homes or in nursing-institutions, everything that is necessary; but for the middle class unwilling to resort to, and indeed regarded as unsuitable for, hospital treatment and yet unable to pay the cost of skilled nursing and attention at home or in a nursing-home, nothing has been done, with the exception of providing a few pay wards in some of the hospitals. The opening of the Empire Hospital in Westminster for the middle class marks a new departure. It is a large up-to-date nursing-home equipped with everything required for the treatment of patients. It is run on business lines, but it is not intended to make larger profits and will provide a reasonable return on the capital invested. The rates charged vary from $15 to $52, and the majority of rooms are from $30 to $40. These terms include board and nursing.

A Defense of the Tuberculous Cow

The question of the relative merits, or rather demerits, of fresh milk which may possibly contain tuberculous bacilli, and sterilized milk, is the subject of correspondence in the *Times*. Mr. Robert Mond, son of the late Dr. Ludwig Mond, the celebrated chemist, has made a series of investigations at his experimental farm and also at the Infants' Hospital, Vincent Square, from which he has come to the conclusion that tuberculosis is not conveyed by cow's milk to man, and further that sterilized or condensed milk is a danger to children fed on it, who are in consequence predisposed to tuberculosis.

Pathologic examinations showed that infection by tubercle bacilli rarely, if ever, occurred from the bowel—as would be the case were milk the agent of transmission. The seat of invasion was ordinarily in the air-passages. Children fed on the milk of cows which subsequently were found to be suffering from tuberculosis had not contracted the disease. On the other hand, at the Infants' Hospital a large number of those children who were fed exclusively from birth on sterilized or condensed milk, which of course could be guaranteed tubercle-free, developed tuberculosis of the bovine type. The term "bovine" must not be taken to imply that a particular form of infection had been passed on from cattle to human beings. It is quite as reasonable to suppose that human beings had infected cattle originally as that cattle had infected human beings. The children were always weak and ill-nourished. This suggested that the cause might be the food. As a control experiment, a number of kittens were fed exclusively on sterilized milk; they all died in a fortnight. Mr. Mond was so impressed by these facts that he drank the milk of tuberculous cows in large quantities and found that he thrived on it. He would not have dared to use that milk sterilized. They take, he added, healthy children into crèches and feed them on sterilized milk and make them ill. But for the unsterilized cream added to the milk the children would die. It is curious that the advocates of sterilization have overlooked butter, which is just as likely to be contaminated as milk. The fact is that butter saved the unfortunates condemned to live on boiled milk. Mr. Mond regards milk as a living fluid intended by Nature for immediate consumption. If boiled it is chemically changed and loses in nutritive value. The chief danger in regard to milk is contamination, and the object of reformers should be greater cleanliness in the dairies and improved means of storage.

Sir Almroth Wright, discussing Mr. Mond's views, states that the question is so important that it should be taken up by the state and investigated scientifically. He has demonstrated that when milk is boiled the lime and magnesium salts are precipitated and settle at the bottom of the vessel. If, however, a drop of acid be added the lime-salts are again dissolved. Thus in the case of milk sterilized by boiling the child is deprived of these important constituents. Milk is a complex fluid beautifully balanced as regards its various constituents and containing all the essentials of nutrition. The loss or decrease of a particular constituent must affect the value of the milk. Sir Almroth thinks that too much is being made at present of so-called exclusion of infection, and hygiene. Infection cannot be completely excluded. The well-fed, well-nourished child possesses powers of resisting disease which are its best protection.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Jan. 9, 1914.

Salvarsan Effects Counteracted by Epinephrin

At one of the last sessions of the Société française de dermatologie et syphiligraphie, Dr. Milian, physician of the hospitals of Paris, made an interesting report on this subject. The complications which follow injections of salvarsan are not due, according to Milian, to the toxicity of the drug, which possesses scarcely any organotropic power, but are mainly connected with the mechanical troubles due to its vasodilating power. Those who are intolerant of salvarsan are generally subjects with insufficient vascular tone. This being the case, Milian thought that such patients might benefit by the preventive use of epinephrin. Although in an old syphilitic who had been subject for two years to epilepsy, each of four intravenous injections of neosalvarsan (in dose of from 0.3 to 0.35 gm.) caused violent reactions, the fifth injection of 0.45 gm. of neosalvarsan accompanied by an intramuscular injection of 0.0015 gm. epinephrin caused no reaction. Violent reaction followed the sixth injection, used without epinephrin. An intramuscular injection of 0.0015 gm. epinephrin was given before the seventh dose of neosalvarsan, which, though higher (0.5 gm.) caused no reaction whatever. Similar observations have been made on other patients, especially a physician who scarcely tolerated 0.45 gm. of neosalvarsan and took 0.6 gm. very badly, but was not inconvenienced by doses of 0.9 gm. after injections of epinephrin.

Milian generally injects from 0.0015 to 0.0002 gm. of epinephrin, according to the intensity of the reactions previously observed. The injection, he says, should be intramuscular, not subcutaneous, to avoid too rapid elimination. Intravenous injections should be reserved for cases in which quick action is necessary, as when grave symptoms manifest themselves, such as those of serous apoplexy. These occur usually on the third or fourth day after an injection of salvarsan, so that it is advisable to prolong the effect of the epinephrin injected by administering the drug by mouth, six times daily, in 0.25 mg. doses.

Heavy Intravenous Injections of Glucose Solutions

On January 6, Dr. Enriquez, physician of the hospitals of Paris, reported to the Académie de médecine the good results which he obtained from the intravenous injection of 300 per cent. glucose solutions. These were made so slowly that the injection of from 250 to 300 c.c. of glucose solution lasted about an hour. One patient often received in two or three injections as much as a liter (about one quart) of glucose solution, which represents 300 gm. of sugar, an allowance equal, as is well known, to about 1,200 calories. The tolerance of the organism to these injections is perfect.

In a great number of various infectious conditions at the stage at which the *myocardium no longer responds to the usual stimulants*, the effects of these injections have been remarkable, in most cases producing an almost immediate diuresis and a rapid improvement of the general condition. The same beneficial action has been noticed in several cases of serious intoxication (carbon monoxid and chloroform). Enriquez has also used these injections successfully in cases of more or less marked inanition due to ulcerous or stenotic lesions of the alimentary canal or to acute appendicitis, etc.

Intravenous injections of glucose solution offer to the clinician a weapon of the first order in the numerous cases of mechanical oliguria symptomatic of hyposystolic or asystolic conditions. Used after a loss of blood, these injections cause an immediate diuresis, which will be abundant in proportion to the amount of functional integrity of the kidney, and make it possible to await the slower action of the cardiac remedies.

The Journal of Radiology and Electrology

An addition to the excellent *Archives d'électricité médicale*, which for many years has been edited by Dr. Bergonié, professor of electrotherapeutics at the Faculté de médecine de Bordeaux, there has just been founded a *Journal de radiologie et d'électrologie*. The first number has just appeared and contains an article by J. Belot on the roentgenography of the maxillaries and of the teeth, a study by Guilleminot and Zimmern on the nature of the Roentgen ray and a general review by Delherm and Laquerrière on electricity in the treatment of infantile paralysis.

Marriages

Charles Lock Kennedy, M.D., Laurel, Ohio, to Miss Carrie Schlottenbeck of New Richmond, Ohio, at Batavia, Ohio, December 31.

Hilbert Francis Day, M.D., to Miss Elizabeth Vernor Henry Richards, both of Boston, at Middlebury, Conn., January 3.

Asst.-Surg. John Joseph O'Malley, U. S. N., to Miss Mildred Fendall Jones of Washington, D. C., January 7.

W. H. Alonzo Warner, M.D., East Orange, N. J., to Miss Natalie B. Feraud of Redlands, Cal., December 31.

William Glenn Miller, M.D., Morrisville, Mo., to Miss Edith Louise Dixon of Welsh, Okla., December 31.

Asa Charles McCurdy, M.D., to Miss Frances W. Starkey, both of Battle Creek, Mich., January 12.

W. W. Everett, M.D., Highland, Ill., to Miss Laura Vulliet of St. Louis, at Hope, Ark., January 8.

Preston Hunt, M.D., Texarkana, Tex., to Miss Hattie Hutton of Ballinger, Tex., January 5.

Arthur D. Sinclair, M.D., to Miss Kathryn J. Blake, both of Toronto, Ont., December 15.

Timothy J. Dwyer, M.D., to Miss Susan M. Flanagan, both of Omaha, Neb., January 7.

Henry Michie Schneider, M.D., to Miss Lena Meyer, both of Cincinnati, January 10.

Louis C. Herchenroeder, M.D., to Mrs. Minnie Moss, both of St. Louis, January 8.

Adolph B. Oyen, M.D., to Miss May Johnson, both of Chicago, January 15.

Deaths

Edward Charles Spitzka, M.D. New York University, New York City, 1873; a member of the Medical Society of the State of New York, and the New York Academy of Medicine; in 1890 president of the American Neurological Association, and in 1893 president of the New York Neurological Society; author of a well-known treatise on insanity; a specialist on internal diseases, particularly of the nervous system; consulting neurologist in the Sydenham Hospital, New York City; editor of the *American Journal of Neurology* from 1881 to 1884; died at his home in New York City, January 13, from cerebral hemorrhage, aged 61.

Henry Ader, M.D. Philadelphia School of Medicine and Surgery, 1869; Cincinnati College of Medicine and Surgery, 1876; a Fellow of the American Medical Association; died at his home at Somerset, Ind., January 3, aged 69. At a special meeting of the Wabash County Medical Association, resolutions of respect and regret were adopted.

James Dallas Croom, M.D. Medical College of the State of South Carolina, Charleston, 1876; a member of the Medical Society of the State of North Carolina; for 42 years a practitioner of Maxton; a Confederate veteran; a member of the local school board and director of the Bank of Maxton; died at his home, January 6, aged 69.

Carl Bernard Cranmer, M.D. Jefferson Medical College, 1898; a member of the Medical Society of the State of Pennsylvania; for several years physician for the Jefferson and Clearfield Coal and Iron Company at Iselin; died suddenly at the home of his parents at Monroetown, December 21, from nervous breakdown.

Edward William Malone, M.D. College of Physicians and Surgeons, Chicago, 1885; formerly a Fellow of the American Medical Association; a member of the State Medical Society of Wisconsin; at one time physician of Waukesha County; died at his home in Waukesha, January 9, from cerebral hemorrhage, aged 58.

William Bernhardt Fehring, M.D. Rush Medical College, 1903; assistant professor of obstetrics and gynecology in his Alma Mater; a member of the staff of the Presbyterian Hospital; a Fellow of the American Medical Association; died at his home in Chicago, January 10, from diabetes, aged 39.

Emma Florence Richardson, M.D. University of Iowa College of Homeopathic Medicine, Iowa City, 1893; president of the Cedar Rapids Society for the Prevention of Cruelty to Animals, and humane officer of Cedar Rapids; died at her home in that city, January 7, from cerebral hemorrhage, aged 57.

John R. Sinks, M.D. Barnes Medical College, St. Louis, 1907; of Spokane, Wash.; formerly a Fellow of the American Medical Association; a member of the Washington State Medical Association; died at the home of his parents in Spokane, January 5, from septic pneumonia, aged 30.

Edwin De Baun, M.D. New York Homeopathic Medical College, New York City, 1885; visiting physician to St. Mary's Hospital, Passaic, N. J.; died at his home in that city, January 7, from the effects of a gunshot wound, self-inflicted, it is believed, with suicidal intent, aged 59.

Richard Vaux L. Raub, M.D. Jefferson Medical College, 1896; a member of the Medical Society of the State of Pennsylvania; for several years a president of the borough council; and president and treasurer of the borough school board; died at his home in Quarryville, January 2, aged 41.

Thomas Renick Hayes, M.D. Chicago Medical College, 1864; a Fellow of the American Medical Association; for many years a highly esteemed practitioner of Bellefonte, Pa.; died at his cottage in Atlantic City, N. J., January 3, from fatty degeneration of the heart, aged 74.

Clinton Helm, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1852; medical director of volunteers during the Civil War, and a prisoner in Libby Prison; for many years a practitioner of Rockford, Ill.; died at his home in that city, January 14, aged 84.

Jefferson Davis Gober, M.D. Louisville Medical College, 1888; a member of the State Medical Association of Texas; for 20 years a practitioner of Beaumont, Tex.; died at his home in that city, January 2, from nephritis, aged 52.

Erastus Ranney Ellis, M.D. Cleveland University of Medicine and Surgery, 1857; at one time professor of surgery in the Detroit Homeopathic College; died at his home in Detroit, January 7, aged 81.

Deaths

Edward Charles Spitzka, M.D. New York University, New York City, 1873; a member of the Medical Society of the State of New York, and the New York Academy of Medicine; in 1890 president of the American Neurological Association, and in 1893 president of the New York Neurological Society; author of a well-known treatise on insanity; a specialist on internal diseases, particularly of the nervous system; consulting neurologist in the Sydenham Hospital, New York City; editor of the *American Journal of Neurology* from 1881 to 1884; died at his home in New York City, January 13, from cerebral hemorrhage, aged 61.

Henry Ader, M.D. Philadelphia School of Medicine and Surgery, 1869; Cincinnati College of Medicine and Surgery, 1876; a Fellow of the American Medical Association; died at his home at Somerset, Ind., January 3, aged 69. At a special meeting of the Wabash County Medical Association, resolutions of respect and regret were adopted.

James Dallas Croom, M.D. Medical College of the State of South Carolina, Charleston, 1876; a member of the Medical Society of the State of North Carolina; for 42 years a practitioner of Maxton; a Confederate veteran; a member of the local school board and director of the Bank of Maxton; died at his home, January 6, aged 69.

Carl Bernard Cranmer, M.D. Jefferson Medical College, 1898; a member of the Medical Society of the State of Pennsylvania; for several years physician for the Jefferson and Clearfield Coal and Iron Company at Iselin; died suddenly at the home of his parents at Monroetown, December 21, from nervous breakdown.

Edward William Malone, M.D. College of Physicians and Surgeons, Chicago, 1885; formerly a Fellow of the American Medical Association; a member of the State Medical Society of Wisconsin; at one time physician of Waukesha County; died at his home in Waukesha, January 9, from cerebral hemorrhage, aged 58.

William Bernhardt Fehring, M.D. Rush Medical College, 1903; assistant professor of obstetrics and gynecology in his Alma Mater; a member of the staff of the Presbyterian Hospital; a Fellow of the American Medical Association; died at his home in Chicago, January 10, from diabetes, aged 39.

Emma Florence Richardson, M.D. University of Iowa College of Homeopathic Medicine, Iowa City, 1893; president of the Cedar Rapids Society for the Prevention of Cruelty to Animals, and humane officer of Cedar Rapids; died at her home in that city, January 7, from cerebral hemorrhage, aged 57.

John R. Sinks, M.D. Barnes Medical College, St. Louis, 1907; of Spokane, Wash.; formerly a Fellow of the American Medical Association; a member of the Washington State Medical Association; died at the home of his parents in Spokane, January 5, from septic pneumonia, aged 30.

Edwin De Baun, M.D. New York Homeopathic Medical College, New York City, 1885; visiting physician to St. Mary's Hospital, Passaic, N. J.; died at his home in that city, January 7, from the effects of a gunshot wound, self-inflicted, it is believed, with suicidal intent, aged 59.

Richard Vaux L. Raub, M.D. Jefferson Medical College, 1896; a member of the Medical Society of the State of Pennsylvania; for several years a president of the borough council; and president and treasurer of the borough school board; died at his home in Quarryville, January 2, aged 41.

Thomas Renick Hayes, M.D. Chicago Medical College, 1864; a Fellow of the American Medical Association; for many years a highly esteemed practitioner of Bellefonte, Pa.; died at his cottage in Atlantic City, N. J., January 3, from fatty degeneration of the heart, aged 74.

Clinton Helm, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1852; medical director of volunteers during the Civil War, and a prisoner in Libby Prison; for many years a practitioner of Rockford, Ill.; died at his home in that city, January 14, aged 84.

Jefferson Davis Gober, M.D. Louisville Medical College, 1888; a member of the State Medical Association of Texas; for 20 years a practitioner of Beaumont, Tex.; died at his home in that city, January 2, from nephritis, aged 52.

Erastus Ranney Ellis, M.D. Cleveland University of Medicine and Surgery, 1857; at one time professor of surgery in the Detroit Homeopathic College; died at his home in Detroit, January 7, aged 81.

John Wylie Hagler, M.D. University of Alabama, Mobile, 1894; a member of the Medical Association of the State of Alabama; for several years a practitioner of Prattville; died in the Williamson-Faulk Infirmary, Tuscaloosa, January 3, from erysipelas, aged 44.

Mordecai Davis Elder, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1878; a Fellow of the American Medical Association; one of the oldest practitioners of Bourbon County, Kan.; died at his home in Mapleton, December 18, from angina pectoris, aged 65.

James L. Reilly, M.D. Chicago Medical College, 1889; a trustee of the Chicago Industrial School for Girls; formerly a member of the American Medical Association; died in Mercy Hospital, Chicago, January 15, from pneumonia, aged 53.

Alexander Coleman, M.D. King Eclectic Medical College, Des Moines, Iowa, 1884; formerly a member of the Nebraska state legislature; later a resident of Rocky Ford, Colo.; died at the home of his son in Selma, Cal., December 28, aged 62.

Thomas Edwards Converse, M.D. Hospital College of Medicine, Louisville, 1892; formerly a specialist on diseases of the eye, ear, nose and throat of Louisville; died at his home in Hanover, Va., January 4, from pneumonia, aged 44.

Wilhelm Thies, M.D. Jefferson Medical College, 1877; a member of the Illinois State Medical Society; for 27 years a practitioner of Chicago; died suddenly in Janesville, Wis., January 14, from heart disease, aged 61.

Benno Albrecht Hollenberg, M.D. Memphis Hospital Medical College, 1885; a Confederate veteran; for nearly fifty years a practitioner of New York City; died at his home, January 1, from heart disease, aged 73.

George William Peckham, M.D. University of Michigan, Ann Arbor, 1881; formerly superintendent of schools and public librarian of Milwaukee; died at his home in that city, January 10, aged 68.

William L. Broaddus, M.D. New York University, New York City, 1868; a member of the Medical Society of Virginia; a Confederate veteran; died at his home in Bowling Green, January 4, aged 67.

Frank Byron Brooks, M.D. University of Syracuse, N. Y., 1881; for nine years instructor and lecturer on physiology in his Alma Mater; died at his home in Syracuse, December 26, aged 58.

Abby Swan Morse, M.D. Boston University School of Medicine, 1875; of Gloucester, Mass.; died in the Addison Gilbert Hospital in that city, December 2, from appendicitis, aged 68.

Daniel Eastman Rogers, M.D. Harvard Medical School, 1901; of Center, N. D.; died in the Mandan (N. D.) Hospital, December 31, from appendicitis, three days after operation, aged 36.

Adolph E. Linder, M.D. American Medical College, Eclectic, St. Louis, 1897; died at his home in East St. Louis, December 27, from rheumatic endocarditis, aged 42.

John Fisher Keene, M.D. Western Reserve University, Cleveland, Ohio, 1893; died at his home in Gustavus, Ohio, December 24, from cerebral hemorrhage, aged 46.

Harvey Le Roy Smith, Ph.G., M.D. College of Physicians and Surgeons, Chicago, 1906; died suddenly at his home in Chicago, January 7, from heart disease, aged 41.

Charles Clay Miller, M.D. Rush Medical College, 1891; of Boulder Creek, Cal.; died at his home in that city, December 23, from general nervous breakdown

William Joseph Byrne, M.D. St. Louis College of Physicians and Surgeons, 1901; died at his home in Dubuque, Iowa, December 25, aged 33.

Joseph Francis De Silver, M.D. University of Pennsylvania, Philadelphia, 1900; died at his home in Atlantic City, N. J., January 1, aged 38.

Levi Shoemaker, M.D. Eclectic Medical Institute, Cincinnati, 1887; died at his home in Wyanet, Ill., December 18, aged 59.

George Kennon Taylor, M.D. Bellevue Hospital Medical College, 1886; died at his home in Cincinnati, December 26, aged 76.

W. S. Woolford, M.D. University of Arkansas, Little Rock, 1884; died at his home in Kingsland, Ark., December 24, aged 57.

Charles A. Pusheck, M.D. Hahnemann Medical College, Chicago, 1880; died at his home in that city, January 1, aged 54.

Charles Louis Goehring, M.D. Jefferson Medical College, 1871; died at his home in Pittsburgh, December 31, aged 70.

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

EXPURGO (SANOL) ANTI-DIABETES

One More Fraudulent Nostrum for Diabetes

Expurgo Anti-Diabetes is sold and advertised in the United States by the Expurgo Manufacturing Company, Chicago. The concern is the United States branch of a Canadian company, the Sanol Manufacturing Company, Ltd., Winnipeg, which sells its product in Canada under the name of "Sanol Anti-Diabetes." The parent company is said to have been incorporated under Manitoba laws in 1912 and to have for its officers and directors the following men:

Charles Beyer, President
Frank Beyer, Vice-President
Charles Bauer, Secretary-Treasurer and Manager.

The manager of the United States branch in Chicago is said to be one E. M. von Amerongen.

The stuff is such an evident fraud that one would imagine that even intelligent laymen could not be deceived by it. Nevertheless medical journals both in the United States and Canada have accepted advertisements for this preparation and physicians—of a certain type—have been found to give testimonials for it. The medical profession is circularized widely by the concern and "write-ups" have appeared in pseudo-medical journals. Some of the claims made for Expurgo Anti-Diabetes are:

> "The only positive cure for Diabetes."
>
> "It never fails to effect a Cure in every case of this disease, in whatever form it may present itself provided the patient has not reached the last stages of the malady."
>
> "Expurgo Anti-Diabetes is the New Cure for this deadly affliction."
>
> "Diabetes is certainly curable by our new discovery—Expurgo Anti-Diabetes, provided that the course of the disease has not progressed to the extent that the vital organs are irreparably damaged."
>
> ". . . thanks to the discovery of Expurgo Anti-Diabetes, the cure of this dread disease is no longer a matter of doubt."
>
> "With the exception of very advanced cases of Diabetes . . . all diabetes can be cured by Expurgo Anti-Diabetes."

Such claims one would imagine would be more than sufficient to make plain, even to the most uncritical of physicians, the evident fraudulence of Expurgo Anti-Diabetes. Nevertheless, the advertisements of this fraud have appeared during 1913, in the following medical journals:

Medical Times
Medical Brief
Medical Summary
Buffalo Medical Journal
Louisville Monthly Journal
Iowa Medical Journal
Canada Lancet
Detroit Medical Journal
Medical Herald
Medical Review of Reviews
Medical Standard
Medical Review
Therapeutic Record
Medical Fortnightly
Indianapolis Medical Journal
Southwest Journal of Medicine and Surgery
Western Canada Medical Journal
Dominion Medical Monthly
Canadian Medical Association Journal
Canadian Practitioner and Review
Massachusetts Medical Journal

Physicians will recognize that, with but few exceptions, most of these journals are utterly unrepresentative of scientific medicine.

The *Army and Navy Medical Record* shown in The Journal recently as a journalistic fraud, contained an editorial puff of Expurgo Anti-Diabetes. The fact that the Expurgo Company reprints the "editorial" from the *Army and Navy Medical Record* as a "voluntary and unsolicited reference" and distributes it among physicians, indicates how rotten are the props on which the superstructure of this fraud rests.

Another alleged "voluntary and unsolicited reference" used by the Expurgo Company, is taken from the *Therapeutic Record* of Louisville, Kentucky. The advertising pages of the *Therapeutic Record* reek with frauds and it has more than once given editorial endorsement to some of the frauds that it advertises. The following enlightening letter is alleged to have been written by the editor of the *Therapeutic Record* to the Expurgo Company in February, 1913:

> *Gentlemen:*—Your favor of February 14th came duly to hand. Let me advise you to pay no earthly attention to the proceedings of the Medical Society where your product was criticized. These people exert no influence with the practical up-to-date element of the profession and are doing you as they do others. *Never fear—you will succeed—your remedy is all right. No man can talk down a meritorious product. I stand ready to help you in any way at any time.*
>
> With sincere regards, I am,
>
> Robert C. Kenner, M.D.,
> Editor, the *Therapeutic Record.*

This, it will be noticed, was written in February. Soon thereafter the *Therapeutic Record* was carrying the Expurgo advertisement, and the June, 1913, issue contained a puff on Expurgo, entitled "A Contribution to the Medical Treatment of Diabetes." The *quid pro quo* is fairly evident.

THE ALLEGED FORMULA

The formula for this nostrum is never published, although in some of the advertising matter it is claimed that it is "at the disposal of physicians." A physician wrote to the Expurgo Manufacturing Company, asking for the formula. He was told that the preparation was "exclusively derived from the vegetable kingdom," from which one may recognize a family likeness to the "dope" put out by the immortal Lydia Pinkham. Further, to copy the letter exactly:

> "The ingredients of which Antidiabetes is composed are chiefly:
> "fructus syzigii jambulani
> "cortex syzigii jambulani
> "flores Rosmarini
> "fructus Anisi stellati
> "Extr. fl. Colæ
> "Extr. fl. Condurango
> "Extr. fl. Chinæ spir. spiss.
> "Extr. fl. Calami
> "Extr. fl. Gentianæ."

The recipient of this noncommittal and uninforming "formula" again wrote the Expurgo Manufacturing Company, asking for quantities. Evidently this nostrum concern considered such a request a piece of impertinent inquisitiveness, for it replied to the physician in these terms, given *verbatim et literatim:*

> "*Dear Sir:*—Yours of the 16th duly to hand. We note that you state '. . . I do not like to be working in the dark, and you can readily see that this is the case unless I know how much of each ingredient I am giving. . . .'
>
> "In your letter of the 6th you asked for the composition, which you promptly received. We would like to state that we are dealing with about 600 Doctors. Some of them asked for the formula, which they received. These are all very conscientious gentlemen and none of them ever pretended 'to work in the dark.' You know furthermore that none of these ingredients is harmful in any way and yet 'work in the dark.' You know that if there were any harmful ingredients in our preparations, we would expose ourselves to imprisonment. If you are so anxious to know all about it, why do you not analyse our medicine? This would enlighten you in your 'perfect darkness.' If you want to deprive your patients and yourself of the indisputable good of our preparations, simply do not prescribe them. Why finally do you not write to the Doctors whose names we gave, who know enough to be able to enlighten those who need it.
>
> Truly yours
> The Expurgo Mfg. Co.,
> C. M. v. Amerongen, Manager.

More than a year ago, a Wisconsin physician, *himself a* sufferer from diabetes, wrote The Journal that for three months he had been using Expurgo Anti-Diabetes which the Expurgo people had sent him. He declared that the nostrum had greatly reduced the percentage of sugar in his urine. In its reply, The Journal asked him whether, in testing his urine, he had used portions of twenty-four hour specimens or merely individual specimens. His attention was called to the fact that most of the nostrums for diabetes are diuretics which, by increasing the amount of urine passed, give an apparent decrease in the amount of sugar excreted. A few days later, the physician wrote again, stating that he had committed the very error The Journal had suspected, and reporting that an examination of a twenty-four-hour specimen showed that the glucose-excretion, instead of being diminished, actually increased. This matter was referred to editorially in The Journal, Nov. 9, 1912, under the title, "A Possible Fallacy in Testing Diabetic Urine."

Specimens of Expurgo Anti-Diabetes were examined in the Association's laboratory and the chemist's report follows:

LABORATORY REPORT

"The specimen of Expurgo Anti-Diabetes (Sanol's Anti-Diabetes) examined, was a light-brown, opaque liquid, having a faintly aromatic odor and bitter taste. The specimen contained considerable amounts of brown, insoluble residue resembling the deposits often found in fluid extracts. The absence of ammonium salts, iodids, glycerin, hexamethylenamin, of antipyrin, pyramidon and similar substances and of such purgatives as aloes, frangula, rhubarb, etc., was indicated. Potent alkaloids such as aconitin, cocain, morphin and strychnin were not found. Qualitative tests indicated the presence of traces of phosphates, sulphates, reducing sugars, caffein and cinchona alkaloids. Alcohol was present only in traces. Small quantities of chlorids, sodium and a salicylate were found. The residue on drying amounted to 2.9 gm. in each 100 c.c. A determination of the salicylic acid indicated approximately 0.17 gm. in each 100 c.c., which is equivalent to less than 0.2 gm., of sodium salicylate per 100 c.c. (about 1 grain to the ounce). Evidently the preparation contains plant extractives in aqueous solution and small amounts of sodium salicylate and sodium chlorid."

Summed up, the chemist's report shows that Expurgo Anti-Diabetes is essentially a watery solution of plant extractives with small quantities of sodium salicylate and salt. The exploiters claim their stuff contains the fruit and bark of jambul, rosemary, star anise. and fluid extract of calamus, cinchona, cola, condurango and gentian. Since fluidextracts in general are strongly alcoholic and since the laboratory's analysis shows that the preparation contains only traces of alcohol, the fluidextracts of the various drugs, if present at all, must be in an infinitesimal amount.

Chicago,____________191___

The letter head of the Expurgo [illegible] the claim that Expurgo Anti-Diabetes [illegible] for diabetes." And this stuff is foisted [illegible] the medical press!

Jambul was in vogue as a remedy for diabetes about twenty years ago. It was tried and found wanting, and has long since been relegated to the therapeutic scrap heap. Sanol therefore, is but one more proprietary humbug, foisted on the profession under fraudulent claims, and having for its essential constituent a drug that has long been discarded by scientific men and resurrected for the purposes of quackery. Expurgo will probably be used by uncritical and unthinking physicians and its existence will be artificially prolonged through the venality of pseudo-medical journals. That the medical profession should tolerate such an evident fraud is not to its credit. There is no excuse, either moral or otherwise, for a physician giving his patients nostrums of whose composition he is ignorant, and that is what is done whenever Expurgo Anti-Diabetes is prescribed.

PRESCRIBING IN THE HOSPITAL

The following paragraphs are from a letter by the president of the visiting staff of a large hospital which is revising the entire question of drugs:

"We hope to eliminate many time-honored formulas, increase the simplicity of prescriptions, use only approved drugs, cultivate among the interns a rational drug therapy in line with the plans of the American Medical Association in that direction, etc.

"It has occurred to me that perhaps you could put us in touch with the hospitals that have already gone over this ground, or perhaps some individual physicians that you may know could help us in that direction."

We print the foregoing for two reasons: first, because we hope to learn of other hospitals which have taken this step, and second, because we trust it may arouse other institutions to make a revision of their methods.

The convenient but lazy and unscientific method of prescribing by number has a pernicious influence. Those who employ this method cannot adapt their prescribing to the individual patient. They prescribe a tonic mixture, giving perhaps three, four or more harmful or useless drugs for the sake of an effect that most probably could be obtained from one simple bitter. The morphin, or one of its derivatives, in the ordinary cough-mixture may be needed only for certain stages; only one or more of the other ingredients are wanted, but the "shotgun" mixture is given rather than write a special prescription. Students who have been trained to prescribe by such a method finally succumb to this habit, and when they enter practice are ready to accept the seductive mixtures of the nostrum-maker. Hence this practice is especially to be condemned when the hospital or dispensary is connected with a medical school. Its evil influence is then multiplied and intensified because it is exerted on the immature minds of students who are always ready to follow the example of their respected instructors. Teachers of pharmacology and clinicians may strive to counteract these influences by their teaching, but the better way is to do away with complicated, ready-to-order formularies altogether. A good rule for any institution to adopt in revising its formulas is embodied in the comment to Rule 10 of the Council on Pharmacy and Chemistry: "The combination of two or more remedies in a mixture must be considered contrary to scientific medicine unless a distinct reason exists for such combination."

Correspondence

The Histopathologic Loan Collection and Relieving the Curriculum

There appeared recently in The Journal (Jan. 10, 1914, p. 125) an article by Steensland and Weiskotten advocating the use of loan collections of slides in teaching pathologic histology, in preference to the method of *giving* to the class each year stained or unstained sections which become the permanent property of the students.

The question of histologic class material comes up now and then in every pathologic laboratory in which teaching is done. Since the choice of the plan of dealing with the problem is rather important, a discussion of the subject seems timely. Steensland and Weiskotten have presented clearly the advantages in the use of the loan collection in teaching, namely, that (1) there is a saving of time for both student and teacher (or technician); (2) the preparations are better stained and mounted, and therefore more satisfactory for demonstration and study, and (3) rare material that would be difficult to replace can be used year after year. They also point out that the practice which the students acquire in staining and mounting sections is not worth the time expended, and that students do not, as a rule, refer to their slides after the course is finished. The last statement may certainly be questioned; but one may grant practically all of the points which the authors make and yet not subscribe to their conclusion. There are at least two reasons, I think, why, in spite of recognized disadvantages, the plan of *giving*, and not lending, histologic preparations is to be preferred:

In the first place, the sense of ownership increases greatly the students' interest in the preparations, and thus indirectly in their work. I have been convinced of this from close observation, and from discussions of the question with third- and fourth-year students who, after having had experience with both methods, have been almost unanimous in opposition to the loan-collection plan. Since fifteen or twenty minutes should suffice for mounting four or five stained sections—the average number given out daily—it would seem that the better spirit and greater interest on the part of the students which the giving of the material undoubtedly induces is rather cheaply obtained.

In the second place, there is for the teacher a more serious objection to the loan-collection plan, namely, the natural encouragement that it gives to cut-and-dried teaching; the lecture is made to fit the slides. For example, if in the prepared collection there are several beautiful sets of slides of chronic nephritis, it is more than likely that these slides will be used year after year, for the effort at staining and mounting from forty to a hundred and fifty more slides from a single new kidney will discourage changes pretty effectively. When the sections are given to the students the same amount of preparation is required for old and for new specimens. The use of loan collections, then, almost invariably tends to make the course inelastic and non-progressive, a condition which, in this time of active investigation and progress in all fields of pathology, is certainly for the teacher and interested student most unfortunate.

Robert A. Lambert, M.D., New York.

A Probable Case of Anilin Poisoning

To the Editor:—Two painters working in the laboratories of the Harvard Medical School with an anilin black stain reported symptoms of poisoning at the end of the day. The formula for the stain which they were using was essentially that described in The Journal, Dec. 20, 1913, p. 2260. It will be remembered that when the solutions are applied and dried the surfaces are washed with hot soap-suds to bring out the black color. The surfaces on which the men were working were about 128 square feet, and it took eight hours to wash them thoroughly. During this time their hands were continually exposed to a hot solution of soap and the chemicals.

From the symptoms, it is entirely probable that they absorbed enough anilin through the skin to cause the poisoning. The men had a sudden onset of very marked general weakness, nausea, marked pallor and cyanotic lips. This condition lasted until nearly midnight in both cases, accompanied by heart symptoms, palpitation mainly, which were severe enough to cause them considerable uneasiness. Apparently as the heart became more normal these symptoms wore off, although one of them reported a violent headache with vomiting which lasted until early the next morning, while the other had a marked diarrhea which persisted throughout the next day. Both reported that the urine the next morning was dark-colored, "like blood." Neither called in a physician and both were able to work the next day. Rubber gloves were furnished them during the washing process and no further trouble was experienced.

E. G. Birge, M.D., Boston.

A Blackmailing Scheme

To the Editor:—I received a letter almost identical with the one given in The Journal, Jan. 10, 1913, p. 153. I answered it stating that I knew of no one who would produce abortion, but that a little later the woman might find a place to stay at the Salvation Army Rescue Home while her child was born. A few days later a western-looking, heavy-set man, clean shaven, about 38 years old, weighing about 165 pounds, having had some old injury to his left hand, called and between sobs and the free use of a handkerchief told me that his niece had bled to death three days before from a criminal operation, and in her hand-bag was found my name and a receipt for some ribbons from a near-by store. He showed me the picture of a girl picking apple-blossoms and asked me if I had ever seen her. I told him no, gave him back her letter and told him what I had written her. He said he believed me, but intended to do everything in his power to find the guilty party. That was all I saw of him that day, but he called several times the next few days to "report progress" and said that they had a woman detective calling on the doctors who stated to each doctor visited that the sister whom the doctor had operated on was not doing very well and wanted to know what was to be done. Each time this man called on me he tried to gain my sympathy by telling me he was so tired out that he was almost sick. The last time he called he seemed quite excited and said he had just received a telegram from home stating that his wife was dangerously ill and for him to return at once. He said he had not enough money for the trip and asked me to lend him the remainder. This I did, for which he gave me his note. This I have put away to remind me what an easy mark a doctor can be.

X. Y., St. Paul, Minn.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

ACTION OF PIGMENT IN INDELIBLE PENCILS

To the Editor:—Particles from the common indelible pencil sometimes get into the eye, where they seem to excite a chemical action on the tissues. Children sometimes bite off and swallow the point. Please inform me with regard to the irritant and toxic action in these cases, and the proper method of dealing with them.

W. C. LIPSCOMB, M.D., Crockett, Tex.

ANSWER.—The substance used most commonly in indelible pencils is methyl violet. This is an antiseptic which is relatively non-toxic. Large doses, however, produce symptoms of poisoning. It is very doubtful if the amount of the point bitten off and swallowed by a child would produce any serious effects. If there is reason to think that the amount swallowed would do harm, an emetic followed by a purgative would be appropriate treatment. The available data are not sufficient to permit an estimate of the probable fatal dose. If a piece has got into the eye, it would seem to be sufficient to wash it out. The trace left would probably do no harm, as this substance has been used as an antiseptic for the eye.

PETROLEUM FOR CONSTIPATION

To the Editor:—1. What is the dose of petroleum used for constipation?

2. Must it be specially prepared?

O. O. KAFER, M.D., Edward, N. C.

ANSWER.—1. The dose is 30 c.c. or 1 ounce two or three times a day.

2. A purified petroleum answering to the official requirements for petrolatum liquidum should be employed. A crude article would be likely to produce too much irritation and might cause poisoning. The description of the official preparation, however, is somewhat loosely drawn, and will permit the use of a somewhat colored article, which may vary widely in specific gravity. A satisfactory product will probably be obtained if the prescription calls for Russian liquid petrolatum or Paraffinum liquidum, B. P.

REMOVAL OF TATTOO MARKS

To the Editor:—Please tell me what to do for tattoo marks. This mark is about 1 by 2 inches on the arm of a young woman.

E. S. SMITH, M.D., Macon, Mo.

ANSWER.—This question was answered fully in THE JOURNAL, Oct. 14, 1912, p. 895. The answer, in brief, is as follows:

> The methods of Variot and of Brault have been recommended for the removal of such marks. The principle in each is to excite an inflammatory process by means of chemical irritants so as to cause destruction of the superficial layers of the skin.
>
> Variot uses as an irritant silver tannate produced by tattooing in a strong solution of tannin and rubbing a silver nitrate pencil over the spot until it is blackened by the formation of silver tannate.
>
> Brault removes the marks by tattooing the surface with a solution of 30 parts of zinc chlorid to 40 parts of water. A slight crust forms after these applications, the spontaneous removal of which after two weeks is followed by a pink cicatrix which gradually becomes of normal color.

ROCKY MOUNTAIN SPOTTED FEVER—TYPHOID FEVER—SCARLET FEVER

To the Editor:—Kindly refer me to late literature regarding Rocky Mountain tick fever and the prophylactic serums and vaccines of typhoid and scarlet fever.

ROBERT W. KING, M.D., Victor, Ida.

ANSWER.—Following is a list of references to recent articles on these subjects:

FORMALDEHYD FUMIGATION

To the Editor:—1. Which is the best method of formaldehyd fumigation: formaldehyd candles, formaldehyd candles with water, formalin solution 40 per cent. in generator or formalin solution 40 per cent. in generator with potassium permanganate? Candles are on the market that are said to be sufficient for 1,000 cubic feet. Are these efficient under ordinary conditions for use in fumigation of dwellings?

2. In conducting bacteriologic tests of formaldehyd fumigation which bacteria should be used as a standard: typhoid, diphtheria, streptococci, staphylococci, colon, or others?

A. H. CALHOUN, M.D., Canton, Ohio.

ANSWER.—1. The method to be recommended is the use of liquor formaldehydi, U. S. P., with potassium permanganate. Our correspondent appears to use the term "formalin" as equivalent to formaldehyd. Formalin in fact is a proprietary solution of formaldehyd containing about 40 per cent. of formaldehyd gas and hence equivalent to liquor formaldehydi, U. S. P.

2. Any one of the organisms mentioned could be used as a test of the efficiency of the disinfection, but the *Bacillus prodigiosus* is the organism usually preferred. The control of the disinfection is accomplished by exposing threads soaked in a culture of *Bacillus prodigiosus*. After the disinfection is completed, these threads are inoculated into Dunham's peptone. If any of the bacilli have survived, the fact will be indicated by the red color of the peptone solution.

LITERATURE ON TRANSMISSION OF DISEASE BY INSECTS

To the Editor:—I should like to have some literature on the transmission of diseases by insects. Can you refer me to any?

F. S. Martin, M.D., Beaumont, Tex.

Answer.—Following is a list of articles on various phases of this subject:

THE HOUSE-FLY

Howard, L. O.: The House-Fly: Disease Carrier, New York, F. A. Stokes Company, 1911, contains an excellent bibliography.
Doane, R. W.: Insects and Disease, New York, Henry Holt & Co., 1910.
Rose, H. H.: Reduction of Domestic Flies, J. B. Lippincott Company, Philadelphia, 1913, price $1.50.
Hodge, C. F.: How You Can Make Your Home, Town or City Flyless, Nature and Culture, 4 West Seventh Street, Cincinnati. Price, 2 cents.
Stockbridge, Frank P.: How to Get Rid of Flies, World's Work, April, 1912.

THE BEDBUG

The Housefly and the B. B., editorial, The Journal, June 29, 1912, p. 2036.
Sergeois, E.: Bedbugs as Carriers of Disease, *Arch. f. Kinderh.*, 1912, lvii; abstr., The Journal, Feb. 24, 1912, p. 594.
Manning, J. C.: Bedbugs and Bubonic Plague, *Med. Rec.*, July 27, 1912.
Riggs, R. E.: Bedbugs as Carriers of Typhoid, *Military Surg.*, September, 1912.

THE WOODTICK

Ricketts, H. T.: The Transmission of Rocky Mountain Spotted Fever by the Bite of the Wood Tick (Dermacentor Occidentalis), The Journal, Aug. 4, 1906, p. 358.
Ricketts, H T.: Further Observations on Rocky Mountain Spotted Fever and Dermacentor Occidentalis, The Journal, Oct. 6, 1906, p. 1067.
Pearse, H. A.: Tick, or Rocky Mountain Spotted Fever, *Denver Med. Times and Utah Med. Jour.*, February, 1909.

OTHER INSECTS

Queries and Minor Notes, The Journal, Oct. 19, 1912, p. 1473; June 24, 1911, p. 1900; Sept. 22, 1911, p. 1076; Nov. 9, 1912, p. 1733, and April 19, 1913, p. 1245.
Doty: The Mosquito: Its Relation to Disease and Its Extermination, New York, Daniel Appleton & Co., 1912, price 75 cents.

ARTICLES ON MEDICAL EDUCATION

To the Editor:—A member of our high-school faculty is preparing to give a series of lectures to the students on the choice of a vocation, expecting to present to them a picture of what is required in the way of education and the future of the various professions and trades. A number of good articles along this line, especially the educational side, have appeared in The Journal within the past year or two; can you give me a list of the articles that you think would be of assistance to him? I expect to place my Journal files at his disposal. C. R. Zener, M.D., Wenatchee, Wash.

Answer.—Following is a list of references to the subject of medical education which have recently appeared in The Journal:

Meltzer, L. J.: The Training of the Desirable Practitioner and His Mission, Aug. 24, 1912, p. 585.
Dodson, J. M.: The Addition of a Fifth Year to the Medical Curriculum, Aug. 24, 1912, p. 589.
Educational Numbers, Aug. 24, 1912, and April 5, 1913.
Adami, J. G.: The Future of the Medical Man, Aug. 23, 1913, p. 526.
Pratt, F. H.: Teacher and Learner in Medicine, Aug. 30, 1913, p. 646.
Guthrie, G. W.: The Passing of the Family Doctor, Nov. 8, 1913, p. 1710.
Bevan, A. D.: Medical Education and the Hospitals, March 29, 1913, p. 974.

BIEBRICH SCARLET STAIN IN DIABETES

To the Editor:—Please describe the method of making a Biebrich scarlet stain of the blood in diabetes.

E. C. Hayman, M.D., Lincoln, Neb.

Answer.—The technic of making a Biebrich scarlet stain of the blood in the determination of diabetes is as follows: Make thick smears of the blood, in the usual way, on glass slides. Allow to dry in the air and fix over the flame. Cover the smears with a 1 per cent. aqueous solution of Biebrich scarlet and allow to remain for a few minutes. Rinse lightly in water and dry. Smears stained in this way will show an intense red if the blood is taken from a diabetic, while normal blood is unstained.

REQUEST FOR REPORTS OF WORK ON PREVENTION OF BLINDNESS

To the Editor:—Through The Journal I desire to ask societies and individuals in the United States engaged in the work for prevention of blindness kindly to forward me reports of this work, or at least to give me the addresses of such societies or individuals. There is no organized work of this sort in the Territory of Hawaii. H. P. Nottage, M.D., 31 Young Building, Honolulu. T. H.

Medical Economics

This Department Embodies the Subjects of Post-graduate Work, Contract Practice, Legislation, *Medical Defense, and Other* Medicolegal and Economic Questions of Interest to Physicians

HARRISON OPIUM BILLS

In The Journal for Aug. 2, 1913, page 360, there appeared an article which outlined in brief H. R. 1967, H. R. 1966 and H. R. 6282 or the "Harrison opium bills," so-called.

All three measures were passed by the House during the special session of Congress last summer, and were referred to the Senate for its concurrence. The first two of these three bills, that is, H. R. 1967 and H. R. 1966, were, according to the *Congressional Record*, Jan. 12, 1914, page 1566, passed by the Senate with slight amendment and returned to the House. Then on the same day, January 12, the lower legislative body by an affirmative vote concurred in the bills as amended so that the two measures await but the signature of the President prior to finally becoming the law.

From the *Record*, it would appear that H. R. 1967, the bill intended to prevent the manufacture of smoking-opium in the United States, was amended by the Senate in chiefly two points, namely, the tax per pound on smoking-opium manufactured in the United States is increased from $200 to $300, and the definition of smoking-opium is broadened in order to include a larger field.

H. R. 1966, the bill intended to prevent the importation of opium for other than medicinal purposes, was likewise amended, but in what regard is not shown in the *Record.*

H. R. 6282, the bill requiring the registration and taxation of physicians and others dealing in habit-forming drugs is, according to latest reports, still in the finance committee of the Senate.

SOCIALIZATION OF MEDICINE IN ENGLAND

Discussion of the British insurance act, its operation and its influence on the practice of medicine, continues to be the most important subject for consideration in the British medical journals. This importance is emphasized by the leading editorial in the first number of the *Lancet* for the new year. Under the title "Humanism and Medicine," the *Lancet* discusses the situation from a sociologic and economic rather than a professional point of view. Starting with the assertion that "the calling of medicine is passing through a very anxious phase," the *Lancet* asserts that the present legislation for national insurance against sickness must be regarded as a phase in the development of medical practice, and that while the machinery and methods by which this development has been brought about may be criticized, and may even be regarded as retrogressive, yet it must be admitted that it has brought about a wider understanding by the public of the essential part that medicine must play in social reform. Using the term "medicine" to designate the work of the scientific medical profession in its widest sense, the writer asserts that the outlook is not one of gloom, but that, on the contrary, the public is demanding that physicians in every branch of their calling should assist in the improvement of the social, moral and physical conditions of the state. One of the most remarkable evidences of the increasing influence of medicine is that a medical side to all things is making its appearance, and that it is being recognized that medicine is essentially one of the branches of human learning that requires the cooperation of humanity in its development. In an interesting comparison between the development of classical learning during the sixteenth century and of scientific knowledge during the nineteenth century, the editor asserts that, previous to the development of modern scientific knowledge, the classics were cultivated because of a conviction that in them was found general instruction in the affairs of life which would be of value to a man in any position of responsibility or service; but to-day, while a classical education still remains valuable, the subjects on which the public instinctively seeks knowledge are those of the natural sciences. With the spread of scientific knowledge it will inevitably follow that the principles of medicine will become familiar to the educated classes, and that this will have a beneficial effect, as true scientific medicine must ever be found on the side of peaceful reform. Enumerating the results already secured, it is pointed out that war between civilized nations is at present more difficult and more easily avoided, because rulers and counselors know that the conditions of warfare are such as to defy the principles of common humanity and cause an enormous amount of avoidable suffering. A growing knowledge of diseases is altering practical geography, as in the case of the construction of the Panama Canal, the control of tropical diseases and the facilitation of commerce and development. Social reform in all nations is based on the teachings of hygiene, whether directed toward eugenics, education or the control or abolition of poverty and disease. The *Lancet* editorial is noteworthy for its far-sighted and clear view, and for its realization of the fact that medicine is becoming socialized, and that the medical profession must alter its methods to conform to this change. That the future of the profession, not only in Great Britain but also throughout the civilized world, will be far greater than its present sphere, admits of no question.

Medical Education and State Boards of Registration

COMING EXAMINATIONS

KANSAS: Topeka, Feb. 9-11. Sec., Dr. H. A. Dykes, Lebanon.

MISSOURI: Jefferson Hotel, St. Louis, Feb. 9-11. Sec., Dr. J. A. B. Adcock, Jefferson City.

NEBRASKA: Lincoln, Feb. 11. Sec., Dr. H. B. Cummins, Seward.

NEW YORK: Jan. 27-30. Mr. Harlan H. Horner, Chief of Examinations Division, Albany.

New Hampshire Reciprocity Report

Mr. H. C. Morrison, regent of the New Hampshire State Board of Medical Examiners, reports that 4 candidates were licensed through reciprocity from Jan. 1 to Dec. 31, 1913. The following colleges were represented:

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
George Washington University	(1908)	Wisconsin
Maryland Medical College	(1912)	W. Virginia
Hahnemann Med. Coll. and Hosp., Philadelphia	(1909)	New Jersey
University of Vermont	(1897)	Vermont

Mississippi October Report

Dr. E. H. Galloway, secretary of the Mississippi State Board of Health, reports the written examination held at Jackson, Oct. 28-29, 1913. The number of subjects examined in was 8; total number of questions asked, 64; percentage required to pass, 75. The total number of candidates examined was 33, of whom 19 passed and 13 failed. For one candidate the report is not yet complete. Four candidates were licensed through reciprocity. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
University of Alabama	(1913)	78
Atlanta College of Physicians and Surgeons	(1913)	82
Tulane University, (1910) 80; (1912) 83+,	(1913)	75, 78, 82, 83
Columbia University, College of Phys. and Surg.	(1913)	86, 88
Medical College of Ohio	(1890)	81
Jefferson Medical College (1910) 84;	(1913)	87
Meharry Medical College	(1913)	77
Memphis Hospital Medical College (1904) 75; (1912) 75;	(1913)	76, 79.
University of Tennessee	(1913)	75

FAILED

College	Year Grad.	Per Cent.
University of Alabama	(1913)	69
Reliance Medical College	(1911)	56
Tulane University	(1913)	71
Mississippi Medical College	(1909)	72
Meharry Medical College (1907) 63;	(1911)	65
Memphis Hospital Medical Coll. (1912) 63;	(1913)	64, 70, 73
University of Nashville	(1906)	71
University of Tennessee (1912) 70;	(1913)	70

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
Northwestern University Woman's Med. School	(1888)	Virginia
University of Louisville	(1897)	W. Virginia
Memphis Hospital Med. Coll. (1905) Tennessee;	(1908)	Tennessee

Utah October Report

Dr. G. F. Harding, secretary of the Utah State Board of Medical Examiners, reports the written examination held at Salt Lake City, Oct. 6-7, 1913. The number of subjects examined in was 19; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 5, all of whom passed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Rush Medical College	(1913)	80.8, 82.1
College of Physicians and Surgeons, Baltimore	(1913)	75.8
Johns Hopkins University	(1913)	84.3
Jefferson Medical College	(1913)	83.9

Utah January Report

Dr. G. F. Harding, secretary of the Utah State Board of Medical Examiners, reports the written examination held at Salt Lake City, Jan. 5, 1914. The number of subjects examined in was 19; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 6, of whom 5 passed and 1 failed. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
Denver and Gross College of Medicine (1906) 87;	(1908)	79
St. Louis University School of Medicine	(1913)	81.4, 85.7
Columbia University	(1913)	84.3

FAILED

College	Year Grad.	Per Cent.
Chicago Physio-Medical College	(1897)	62.2

Oklahoma October Report

Dr. John W. Duke, secretary of the Oklahoma State Board of Medical Examiners, reports the written examination held at Muskogee, Oct. 14-16, 1913. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 70. The total number of candidates examined was 9, of whom 8 passed and 1 failed. Thirteen candidates, including 1 osteopath, were licensed through reciprocity since July, 1913. The following colleges were represented:

PASSED

College	Year Grad.	Per Cent.
University of Arkansas	(1913)	86
Bennett Medical College	(1913)	86
University of Illinois	(1912)	78
Tulane University	(1913)	78
University of Michigan, Dept. of Med. and Surg.	(1913)	84
University of Oklahoma	(1913)	83
Jefferson Medical College	(1911)	84
Baylor University, College of Medicine	(1913)	71

FAILED

College	Year Grad.	Per Cent.
College of Med. and Surg., Physiomedical, Chicago	(1903)	54

LICENSED THROUGH RECIPROCITY

College	Year Grad.	Reciprocity with
University of Arkansas	(1912)	Arkansas
Atlanta College of Physicians and Surgeons	(1902)	Texas, (1902) Mississippi.
Georgia Coll. of Eclectic Med. and Surg.	(1880)	Arkansas
Bennett College of Eclectic Med. and Surgery	(1879)	New Mexico
Kentucky University, Medical Dept.	(1905)	W. Virginia
University of Louisville (1910) Mississippi,	(1911)	Texas

Southwestern University Medical College	(1905)	Arkansas

ANATOMY AND HISTOLOGY

1. Give a short description of the histological structure of bone. 2. Describe and give usual situation of Peyer's patches. 3. What kind of epithelium covers (a) the pleura, (b) the mucous membrane lining the air passages? 4. How would you distinguish a cervical from a dorsal vertebra? 5. Describe the hip joint. Why is there frequently pain about the knee in hip joint disease? 6. Give origin, course, relation to its fellow and the distribution of the optic nerve. 7. At what point does the spinal cord terminate? 8. Give the origin, the course and the principal branches of the great sciatic nerve. 9. Give the origin and the principal branches

of the pneumogastric nerve. 10. Describe the saphenous opening. In what directions would you make taxis in reducing a femoral hernia?

BACTERIOLOGY AND PATHOLOGY

1. Describe the pathological changes that take place in arteriosclerosis. Give the most common cause for same. 2. Name three forms of pulmonary emphysema. Give pathology of each form. 3. Define and give pathology of phlebitis. 4. What is pneumonokoniosis? Give pathology of same. 5. Name three forms of pleurisy. Give pathology of each form. 6. Give method of staining the bacilli of typhoid fever and tuberculosis.. 7. Name four varieties of eczema. Give pathology of each form. 8. Define pathogenic bacteria and name three pathogenic diplococci. 9. Name three methods by which you can determine whether an organ is or is not pathogenic. 10. Name and describe two tests in diagnosing a suspected case of tuberculosis.

CHEMISTRY

1. What are the normal salts; acid salts; basic salts; double salts? 2. Convert Centigrade into Fahrenheit. 3. Complete the equation, $2AgNO_3+2NaOH=?$ 4. What is an element and show what element is common in all acids. 5. Give two tests for morphin. 6. Define allotropism and osmosis. 7. What are albuminoids? Name some of the important albuminoids. 8. Name the halogens and state in what respect they exhibit marked similarity. 9. Give antidotes for strychnine poisoning, also for iodine poisoning. 10. Give Haine's test and the heat and nitric acid tests for urine.

PHYSIOLOGY

1. Define irritability as applied to muscle and nerve, and classify irritants. 2. Is it possible for the human stomach to be digested by its own gastric secretions? If so, under what conditions? 3. What keeps the blood from coagulating in the vessels, and what causes it to coagulate when shed? 4. Describe the mechanism and function of the semilunar valves and tell which one contributes to the second sound of the heart. 5. Name eight conditions affecting body temperature. 6. Give deep origin and distribution of one cranial nerve that has motor function only. 7. Give distribution and function of the tenth cranial nerve. 8. What effect does the injection of atropin into the blood have on the secretion of the salivary glands? 9. Tell the difference between chyle and chyme. 10. The removal of what digestive organ would cause excessive sugar in the urine and death in a short time?

OBSTETRICS AND HYGIENE

1. Differentiate between position and presentation. 2. Name three acute diseases of the mother that endanger the life of the fetus. State the danger to fetus and what steps you would take to prevent it. 3. If on making your first examination of a case of labor you should find a complete placenta previa what would be your line of treatment? 4. What would be your treatment in a case of eclampsia earlier than the eighth month of pregnancy? 5. How would you determine that a fetus was at full term when born? 6. What is the most common cause of a chill on the third day after delivery? What treatment would you use and what precautions to prevent it? 7. What are the symptoms most prominent in extra-uterine pregnancy? 8. How would you conduct a case of post partum hemorrhage? 9. What are the most common pollutions of well water? How free a well from same? 10. What are the best agents for disinfecting a room where small-pox had been treated? How would you proceed?

MATERIA MEDICA AND PRACTICE

1. Give indications for the use of ergot. What is the effect of a toxic dose? 2. Give indications for the use of quinine. How may it effect those having an idiosyncrasy for the drug? 3. Differentiate a functi[illegible] from an organic lesion. 4. Differentiate intercost[illegible]isy. 5. Diagnose and treat apoplexy. 6. Give [illegible] of diphtheria. Typhoid fever. 7. How is iodin obtained? Name some of its uses. 8. In what conditions would you use a poultice? Why? 9. Give indications for the use of veratrum viride. 10. Cerebrospinal meningitis. Give etiology, diagnosis and treatment.

GYNECOLOGY

1. Give etiology and treatment of dysmenorrhea. 2. Diagnose and treat carcinoma of cervix. 3. Name the causes of sterility. 4. Treat gonorrheal endometritis. 5. Diagnose extra-uterine pregnancy before rupture. 6. Give etiology and treatment of amenorrhea. 7. Diagnose and treat uterine polypus. 8. Diagnose carcinoma of the breast. 9. What conditions may result from gonorrhea in women? 10. Differentiate malignant, tubercular and syphilitic ulcer of vagina.

TOXICOLOGY AND MEDICAL JURISPRUDENCE

1. In what diseases is the Argyll Robertson pupil always present? 2. Name fatal dose of zinc chlorid; fatal period and treatment. 3. Name fatal dose of strychnin; fatal period; treatment and post-mortem appearance. 4. Name fatal dose of opium; fatal period and treatment. 5. Name fatal dose of tr. digitalis; fatal period. 6. What is paranoia? Paretic dementia? 7. What is criminal abortion? 8. Give important symptoms of death by throttling: face, mouth, tongue, skin. Post-mortem; heart, lungs, stomach, etc. 9. Give post-mortem findings in death from carbolic acid poisoning. 10. What are the necessary proceedings for the pauper insane?

SURGERY

1. Give the etiology, varieties and symptoms of erysipelas. 2. Describe the surgical methods for the reestablishment of joint functions in confirmed ankylosis. 3. Mention the inflammatory diseases of the bones. 4. What is shock, and how should it be treated? 5. What agents are employed for the production of local anesthesia? 6. What articular changes take place in dislocation? What are the general principles governing the treatment of dislocations? 7. How would you diagnose and treat a case of fracture of both bones of the forearm, occurring at the middle third? 8. What tissues are divided in the operation for oblique inguinal hernia? 9. Differentially diagnose phimosis and gonorrhea from phimosis and subpreputial chancroid. 10. When do the secondary symptoms of syphilis normally appear? What are these symptoms? When do the tertiary symptoms appear?

PHYSICAL DIAGNOSIS

1. What do you understand by the establishment and failure of compensation in valvular heart disease? 2. How many periods or stages are usually met with in the progress of a case of valvular heart disease relative to compensation and failure? Name them. 3. Give some of the common causes of jaundice and the significance of jaundice as a diagnostic symptom. 4. Name diseases in which the knee-jerk is almost absent or completely abolished. 5. What can be felt beneath the normal abdominal walls? 6. Give local signs of appendicitis. 7. Name the five methods usually adopted in examining the thoracic organs. 8. What is understood by asthmatic breathing? By Cheyne-Stokes breathing? By restrained or catchy breathing? By stridulous breathing? 9. Give diagnosis of bronchial pneumonia. 10. What is a crepitant râle?

Book Notices

Principles and Practice of Medical Hydrology. Being the Science of Treatment by Waters and Baths. By R. Fortescue Fox, M.D., F.R., Met. Soc. Cloth. Price, $2. Pp. 295. New York: Oxford *University Press, 1913.*

This book discusses the physiology of bathing, hydrotherapy, mineral springs and baths and the indications for hydrologic treatment. In its preparation Fox has made use of the Hyde lectures of 1911 and other contributions which he has made to balneology. He practiced for twenty years at a British spa, and has produced a volume that is readable, instructive, systematic and founded on sound physiology. He says of spa treatment that it is a vain and fruitless ambition for any locality to introduce and exploit all the methods of other places. *It is not the number of treatments that counts, but* their quality and the skill and discrimination with which they are applied. He remarks that the employment of baths after rheumatic fever is liable to be followed by cardiac debility, and the effect of temperature should be carefully watched. The insidious progressive polyarthritis of young subjects, which is doubtless infective, is accompanied by a profound debility and can seldom, in the judgment of Dr. Fox, be submitted to any form of spa treatment. On the other hand, the arthritis supervening in middle life, always associated with faulty metabolism or defective elimination, clearly marks it out for treatment by waters and baths. The cardinal rule of treatment divides rheumatic cases into two classes—those which require a sedative and those which require a stimulant and intensive treatment. The book abounds in sound, practical advice, and affords help where it is greatly needed. It closes with an index of waters and baths for the guidance of practitioners in selecting spas or medicinal springs for their patients.

Book on the Physician Himself and Things that Concern His Reputation and Success. By D. W. Cathell, M.D., and William T. Cathell, A.M. M.D. Twelfth and Final Edition. Cloth. *Price, $2.50. Pp. 407. Philadelphia: F. A. Davis Company.* 1913.

"The Physician Himself" first appeared in 1882. It was then a comparatively small book. It has grown larger with each edition, until now it is quite a pretentious volume. The title page of this edition carries the statement that it is "the twelfth and final edition." It is seldom that the word "final" is used in such a way, and it is to be hoped that the statement will prove to have been premature. While the book has increased in size with each edition, it has also improved in character, on the principle of the more good things the better. It contains excellent advice and comments on the physician's work, his relations to the profession and to the public, etc. While here and there the views expressed or the comments may not receive the endorsement of every one, on the whole they are excellent. The book is full of good things and good advice, especially for the young physician.

Artificial Parthenogenesis and Fertilization. By Jacques Loeb, Member of the Rockefeller Institute for Medical Research. Translated from the German by W. O. Redman King, B.A., Assistant Lecturer in Zoology at the University of Leeds. Cloth. Price, $2.50. Pp. 312, with 87 illustrations. Chicago: The University of Chicago Press, 1913.

This is essentially a critical summary of Dr. Loeb's work in artificial parthenogenesis. It gives a survey of the methods by which the unfertilized egg (of invertebrates and of vertebrates) can be caused to develop into an embryo, and the conclusions which can be drawn concerning the mechanism by which the spermatozoon produces this effect. Dr. Loeb believes that the fertilization of the egg by the spermatozoon involves two factors, one of the processes being akin to cytolysis, the other (designated the "corrective factor") causing a temporary depression of the oxidation in the egg. Both of these factors are probably independent of the material in the spermatozoon that serves as the vehicle of paternal heredity.

The problem of fertilization is intimately connected with many different problems of physiology and pathology, such as the natural death of the unfertilized egg and the prolongation of its life by fertilization, the fertilization of the egg by foreign blood and the immunity of the egg to the blood of its own species, and the relation between heterogenous hybridization and artificial parthenogenesis. The facts recorded and discussed in the book therefore go beyond the special problem indicated by the title.

The field of artificial parthenogenesis was opened and is to-day essentially dominated by the work of Dr. Loeb and his students, which constitutes one of the most important contributions to cellular physiology of all time. We believe that Dr. Loeb's work will be of greater value in the field of pathologic physiology (growth of tumors) than in the field of normal fertilization and development, and it is to be egretted that the relation of artificial parthenogenesis to umor formation is not discussed at some length in the book. The details of Dr. Loeb's contribution to science are well known to the workers in dynamic biology and physiology. They should be just as familiar to the pathologist and the nternist.

A MANUAL OF SURGERY FOR STUDENTS AND PHYSICIANS. By Francis T. Stewart, M.D., Professor of Clinical Surgery, Jefferson Medcal College. Third Edition. Cloth. Price, $4 net. Pp. 742, with 571 illustrations. Philadelphia: P. Blakiston's Son & Co., 1913.

The appearance of a third edition so soon after the pubication of the second is evidence of the popularity of this book. It is essentially a manual, stripped of unnecessary words and matter, and is therefore a good book for everyday use. Much information is crowded into it, although for fuller discussions, larger and more complete works on surgery must be consulted. The first chapter of this edition is devoted to diagnosis and the Roentgen ray, a decided innovation in text-books on surgery. The text is by no means exhaustive, but nevertheless is of value. Only fourteen pages are devoted to anesthesia, but every known method is discussed, the open ether method being given the preference. Surgical bacteriology, surgical technic, bandaging and surgical pathology are dealt with in an admirably concise but instructive manner. The surgical lesions of each system and viscus are discussed in the succeeding chapter and many illustrations are used to clarify the text. Only one fault is to be found with the book and that is a mechanical one: the type is too small and is set too closely. The eye is tired quickly, and better-made books are apt to be consulted.

UEBER DAS SINNESLEBEN DES NEUGEBORENEN. (Nach physiologischen Experimenten.) Von Dr. Silvio Canestrin, Assistent der Nervenklinik in Graz. Paper. Price, 6 marks. Pp. 104, with 60 illustrations. Berlin: Julius Springer, 1913.

This is a contribution to the psychophysiology of the newborn by means of exact laboratory experiments. Contrary to the older methods of study which made use of the infant's behavior as indicative of pleasure or pain, the author utilizes the differences in the cerebral pulsations and the respiratory curves which occur as a result of various stimuli on the senses, and makes graphic records of these. To prove that a mere look at the child is not sufficient to indicate the inner workings of its primitive psyche, Canestrini cites the following experience: He had occasion to observe a sleeping infant react to acoustic stimuli (the blowing of a trumpet) by an increase in cerebral pulsations and a decrease of the respiratory rhythm, while it continued to sleep, and gave no other visible sign of auditory stimulation. This chance observation led him to undertake a series of experiments on the primitive special senses of the infant, which he recorded. While his results are not far-reaching in their bearings on a correct understanding of the development of human intelligence, they constitute a modest beginning in our recognition of the elementary relations between matter and mind as we can observe them experimentally in earliest infancy. It is possible, as it were, to see the mind grow by external stimulation. The book is worth reading and the experiments worthy of repetition.

DISEASES OF THE STOMACH. Including Dietetic and Medicinal Treatment By George Roe Lockwood, M.D., Professor of Clinical Medicine in Columbia University. Cloth. Price, $5.50 net. Pp. 624, with 141 illustrations. Philadelphia: Lea & Febiger, 1913.

This is an excellent presentation of the subject. The book is not loaded with the extra chapters devoted to anatomy, histology and physiology usually found in such monographs. The author devotes his energy to a discussion of diseases of the stomach and to an account of his own experience in diagnosing and treating them. The detail and thoroughness of the discussion of individual topics is shown by the fact that more than a hundred pages are devoted to a consideration of acute and chronic ulcer and as much more space to malignant and benign tumors or growths in the stomach. Modern methods of diagnosis are described as they are applicable to each disease. Especially helpful are the numerous reproductions of roentgenograms and the discussions of their value in the diagnosis of various diseases of the stomach. This feature is timely and adds greatly to the value of the book, as such discussions have not yet found a place in many of the systematic monographs on diseases of the stomach.

DIE RASSENHYGIENE IN DEN VEREINIGTEN STAATEN VON NORDAMERIKA. Von Géza von Hoffmann, k. u. k. österr.-ungar. Vizekonsul. Paper. Price, 5 marks. Pp. 237. Munich: J. F. Lehmanns, 1913.

This is a popular presentation of the various activities in this country of a eugenic nature with a view to stimulating among *Europeans a greater interest in the eugenic movement.* The author is deeply and favorably impressed with what is being done in that direction in the United States. For the benefit of the German reader there is appended a bibliography of seven hundred titles of American articles and publications in regard to sex hygiene and eugenics, which may be useful to Americans also. American physicians and others will read this book with interest, as it is a sincere effort to give a trustworthy picture of what is being done in the lines indicated.

Miscellany

The Economic Value of Scientific Research.—A lecture on this subject was delivered under the auspices of the Science Association of the Adelaide University, August 6, by Dr. T. B. Robertson, a graduate of the university, now professor of physiologic chemistry in the University of California. The lecturer discussed the questions: 1. Is money expended in furthering scientific research a good investment? 2. What is the actual profit which the world reaps from such investments? 3. Does the money at present expended on scientific research bear any adequate proportion to the profit which may be expected to accrue? In dealing with the first and second questions, Dr. Robertson pointed out that the invention of the electric motor, which resulted from a discovery of Faraday, of which the cost was negligible, had rendered possible the utilization of water-power at a distance. In its waterfalls the United States possessed 37,000,000 potential horse-power, which at about $20 per horse-power per annum, was equal to a yearly income, not yet realized, of about $700,000,000, corresponding at 3 per cent. interest to a capital value of about $24,000,000,000. The total receipts of all the higher institutions of learning in the United States in 1910, was only about $75,000,000, corresponding to a capital investment of about $2,500,000,000. Only a fraction of this was spent in scientific training, and an insignificant fraction of that in research. Yet the inventions which were the consequence of this training and research were worth about $365,000,000 per annum The total endowment of the Rockefeller Institute, the greatest institute for medical research in the world, was only about $4,000,000 Yet in a few years of its existence it had already given them the means of curing two of the greatest scourges of humanity—cerebrospinal meningitis and pneumonia There was at present absolutely no means of automatically securing to scientific research a proportion, however minute, of the wealth it produced A small proportion, even if it were only a few tenths of a per cent of the income proceeding from the utilization of patented inventions, might be appropriated by the state and employed to endow scientific research —*Australasian Med Gaz.*

The Antivivisectionists —The antivivisectionists are having a riotously good time this week (December, 1913) They are assembled in national conclave, and, with the newspapers relaying to the public all they say, each member is outvying the other in wild and irresponsible statements One speaker declared that 33 per cent of the doctors were addicted to the use of drugs It is an appalling statement One doctor in every three has the drug habit! But the most remarkable part of the statement is how a man without the use of drugs could make it

The gentleman who gave a third of our physicians hypothetical injections was soon outdone by some of his colleagues It was jauntily declared that children were being vivisected in New York hospitals and places of medical research The statement was enthusiastically applauded and evidently believed But this orgy of wild statements is nothing new. It is but a repetition of the riot of ignorance that fought every step of medicine's progress in the prevention of smallpox epidemics during the nineteenth century

Vivisection has been made practically painless But even if it had not, it is better that every guinea pig in Ohio should be utilized for experimentation than that your child should die of diphtheria From vivisection we have secured not only the antitoxin that has deprived diphtheria of its terrors, but typhoid vaccine and the serum for the dread disease, spinal meningitis But we have not the space to catalogue the achievements of vivisection Suffice it to say that the wonderful sanitary conditions prevailing in Panama and the canal itself would not have been possible without animal experimentation

The antivivisectionists have been called sentimentalists But which are the true sentimentalists—the physicians who seek scientific truth in a laboratory that they may conserve the life and health of human beings, or the men and women who much prefer the safety of guinea pigs and frogs?—*Cincinnati Times Star.*

Unlicensed Physicians —The secretary of the State Board of Health of West Virginia, according to the *West Virginia Medical Journal*, recently addressed a communication to the attorney general of the state on two interesting questions in connection with the practice of medicine by unlicensed practitioners In that state, it appears, it has been the custom for certain unlicensed physicians to practice under the protection of licensed practitioners, and it is said that the opinion seemed to prevail that this could be legally done The attorney general in his opinion on this point held that an unlicensed physician has no legal right to practice medicine and surgery under the protection of a regularly licensed practitioner either in the same office with him or at any other place Since it has been the experience in West Virginia that in attempting to prosecute unlicensed or irregular practitioners public prosecuting attorneys have declined to conduct such prosecutions, the secretary of the State Board of Health asked the attorney general what recourse the board had against this refusal on the part of the prosecuting attorneys The attorney general said

"If the prosecuting attorney declines to prosecute an unlicensed practitioner when his attention is called to the same by the State Board of Health, the state board should report the fact to the circuit court of the county, and proceedings should be instituted . . to remove him from office."

The law under which proceedings could be instituted is a general one, which provides that if any prosecuting attorney shall compromise or suppress any indictment or presentment without the consent of the court entered of record, he would be guilty of malfeasance in office and may be removed therefrom in the mode prescribed by law. Similar provisions as to malfeasance are in existence in every state, and prosecuting attorneys who fail to do their duty in respect to prosecuting unlicensed practitioners, quacks, etc., may be made to do so, though this would be a cumbersome, expensive and probably ineffective proceeding The secretary of the West Virginia board calls attention to the fact that in the matter of unlicensed and irregular practitioners the proper method for procedure is for local physicians to collect what evidence may be needed and place this in the hands of the prosecuting attorney of the county, insisting on his performing his sworn duty.

The Friedmann Tortoise Bacilli Boom —The history of medicine presents a strange medley of superstition, fads, South Sea bubbles, personal booms, mingled with a vast redeeming amount of devoted searching after truth, and here and there a solid stride ahead in scientific knowledge After all said and done, the world owes an untold debt to the humble and ill requited toilers after truth, who have done more to better the lot of mankind than all the soldiers who have fought for less noble purposes since man first evolved into an animal capable of using arms and of organizing armies. To turn from this picture to that of a German medical man who, by all accounts, has reaped a huge fortune in America from an alleged cure for consumption is, indeed, to look on a counterfeit presentment—two brothers of widely differing character. Dr. Friedmann's curative tortoise serum was not accepted by the orthodox medical profession in the United States, but that fact apparently did not prevent its adoption by a heavily capitalized commercial syndicate Dr Friedmann has since returned to Berlin and, according to recent reports, has at last consented to permit his serum to be used by all German physicians It seems clear that, even under the most favorable circumstances, a long time must elapse before medical experts will be enabled to arrive at definite conclusions as to the value of the remedy, which nevertheless created a record "boom" in the United States —*Med. Press and Circular*, London.

Paralysis During Antirabic Treatment.—With the apparent increase in rabies in the United States and the facilities afforded by biologic laboratories for applying the antirabic treatment of Pasteur so that this treatment may be demonstrated by any physician, it is important to know that, though such sequelae are comparatively rare, a number of cases of paralysis have occurred following this treatment In *Public Health Reports*, Oct 24, 1913, H E Hasseltine of the United States has collated the cases occurring abroad and in this country The article is found in Reprint 148 There seems to be a difference of opinion among neurologists as to the exact lesion of this paralysis Some describe it as a myelitis, others as a neuritis One case showed an ascending paralysis. Among the various theories which account for the paralysis. that of anaphylaxis, resulting from the injection of foreign animal tissue seems to Hasseltine to be the most plausible Stimson reports that there have been seventy six cases with four deaths Hasseltine, from the records of the Hygienic Laboratory of cases of rabies reported from the various Pasteur institutes, has found three cases of paralysis noted. Hasseltine believes it important that physicians should report all such cases

Experimental Insect Transmission of Anthrax —Mitzmain, veterinary entomologist in the government service in the Philippines, in *Public Health Reports*, Jan 9, 1914, reports three positive cases of experimental insect transmission of anthrax The insects used in these expperiments were *Stomoxys calcitrans* and *Tabanus striatus* Owing to the difficulty of telling when the anthrax infection appears in the peripheral blood of the larger animals, guinea pigs were used in these experiments In the first trials the donors were employed from twenty four hours to three days prior to their death, and although characteristic cultures were obtained from the blood, no transfer of infection through the bite of the flies resulted in many experiments. The results were likewise negative when the blood was taken from animals recently dead. In the successful experiments on artificially infected guinea-pigs the flies were applied from two and one-half hours to a few minutes before the death of the guinea-pigs. Other guinea-pigs were used to receive the infected bites of the two insects named. The flies were interrupted while feeding on the sick animal and transferred to the healthy animal in one instance in ten seconds and in another instance at an interval of ten minutes. The exposed animals died in both cases on the third day, and a typical picture of anthrax infection was presented in the necropsy. Similar results were obtained when horse-flies were employed to transfer the disease. Cultures from the experimental guinea-pigs reproduced the disease in a horse. The anthrax organism was found in the feces of all these flies at varying intervals up to nineteen days, and in later experiments the disease was transmitted by biting at twenty-minute intervals after feeding on the infected animal. A series of experiments *is being conducted with anthrax in cattle and horses, and* an attempt will be made to determine the limits of infection in flies acting as carriers.

Medicolegal

Construction, Validity and Importance of Medical Practice Act—Application to Treatment by Suggestion by a "Vitapathic"

(*Smith vs. State* (*Ala.*), *63 So. R.* 28)

The Court of Appeals of Alabama affirms a judgment of conviction of the defendant Smith of treating human diseases without having obtained a certificate of qualification from the State Board of Medical Examiners. The court says that it was admitted that the defendant held himself out and offered to treat and did treat human diseases for a consideration in money; that he gave the patient, in the particular case relied on by the state for conviction, a little bottle of white pills to take internally, and had her place her feet in a tub of water, while holding with her hands the cords of a dry electric battery, which he had placed in the tub; that he diagnosed the case of the patient as that of "general debility," and professed to be able to cure her entirely with ten or twelve of such electrical treatments at $1 per treatment, promising a refund of the money if no good resulted.

The defendant styled himself a "Vitapathic and Scientific Healer," and as a witness in his own behalf explained his system of treatment substantially as follows: "I treat diseases of human beings, rather I bring about a state of thought in the patient which works the healing of disease. It is really the power of mind over matter . . . If we can get a person to really thinking and believing that he is getting better and is going to get well, he will get well. As to the little white pills I give, they are simply a little predigested food . . . I do not give them as a curative remedy, but simply to assist me in getting the patient to the point of believing, on my suggesting it, that he is getting better and is going to get well . . . The reason the use of these things helps me in getting a person to believe in the fact that he is going to get well is because people all over the country are so accustomed to medicine being used as a cure for disease that by the employment of what appears to be such, in connection with my suggestion of health, I can bring about the desired mental action quicker and sometimes more effectively. These means are entirely harmless and ineffective as a remedy, aiding only as a suggestion. Anybody could give the little pills—all of them could be taken without bad effect—and anybody could apply the little battery, a single little dry telephone battery with two little cords attached to it. . . . I do not always use the same thing for the same disease. I sometimes use salves or simple salt water to get the patient's mind in proper condition. In some cases I do not use anything; that is, when without it I can get the attention of the patient and belief on his part in his recovery. . . . There is no hypnotism whatever about my system of treatment. I know nothing about hypnotism. In order for a person to treat diseases on the system or plan I use, or rather in order for a person to be able to bring about a state or mental condition of belief that will result in the cure of disease, it is not necessary for him to understand anything about chemistry, anatomy, physiology, etiology, pathology, symptomatology, and diagnosis of disease; obstetrics and obstetrical operations, gynecology, major and minor surgery, physical diagnosis, diseases of the eye, ear, nose and throat, hygiene or medical jurisprudence. . . . A person without any education whatever can use my system of treatment just as effectively as I can, just so they understand how to bring into play the conscious real mental power resting in every intelligent person. It is the power of mind over matter, over the body. I do not treat persons for broken limbs or in cases of obstetrics, etc., that require surgical assistance."

The court does not doubt that the mind exercises a potent influence over the body, or that its state in many cases has materially to do with the condition of the body; nor does it doubt the efficacy of mental suggestion as a force or agency in leading nature to assert itself and effect a cure of many of the ills that flesh is heir to, or that suggestion may be often effectually aided by the employment on the patient of ineffective, but supposed effective, physical remedies, resembling in kind, but without his knowledge differing in character, from those that he has been accustomed to associate in his mind with and to see used in the cure of disease. For the purposes here, the philosophy of the defendant's treatment may be conceded, even to the full extent of the power he claimed for it, with no limitations on it save those he admitted, and yet the practice of it, in the court's opinion, falls within the inhibition of the law, its letter and purpose, unless the defendant first stands an examination on those branches of medical science or learning hereinbefore enumerated, and receives a certificate of proficiency *therein*—except major surgery, on which he is not required by the law to stand an examination if he states in writing before the examiners that he does not propose to employ that in his practice. (Political code, section 1626 et seq.; Criminal code, section 7564.)

The section of the criminal code cited is a part of the same act (Act Aug. 7, 1907, p. 591) as that incorporated in the sections of the political code cited. The act mentioned was passed after the decision of *Bragg vs. State*, 134 *Ala.* 165, and therefore with knowledge on the part of the legislature of such decision. Indeed the history of that legislation, as disclosed by the journals of the house and senate and the original bill, in which the act had its inception, will show that that decision gave rise to the legislation, which, while designed in its origin to destroy the effect of that decision, construing the then existing statutes as preventing the practicing of osteopathy without standing the examination then required, culminated in an amended bill, which became the statute here violated, and which, among other changes wrought in the law, broadened the language, as to the class of persons to whom it should be applicable, from those "practicing medicine in any of its branches or departments," the language of the statute construed in *Bragg vs. State*, as extending to osteopaths, to "all persons who treat or offer to treat diseases of human beings by any system of treatment whatsoever," the language of the present statute.

The clause is indeed comprehensive in its scope as to the class of persons on whom the law is to operate; nor is the court prepared to doubt the wisdom of the enactment, or the extensiveness of its intended application. The law leaves the practitioner free to adopt any system or kind of healing or cure that he may see fit, whatever it be, whether it be physical or mental, or both; it requires an examination on no system of therapeutics, and exacts no certificate of proficiency therein. What it *does require is the standing of a* successful examination on those branches of medical learning—chemistry, anatomy, physiology, etiology, pathology, symptomatology, gynecology, diagnosis of disease, physical diagnosis, diseases of the ear, eye, nose and throat—a knowledge of which is deemed necessary to an intelligent understanding of the human body, its composition, organs and their functions, and to an ability to know when it is diseased and when it is not, and, when so, to be able properly to diagnose the trouble, a sine qua non to intelligent treatment of any sort; and a successful examination on hygiene, so that the practitioner will know how to prevent disease and may avoid, at least, the spread and communication to others of the diseases of his patients, or to them of other diseases; and a successful examination on medical jurisprudence, so that, when called to testify as to cases coming under his observation, he may be an intelligent witness, and as such be able to render aid to the courts in the investigation of truth and the administration of the law of the land; and a successful examination on obstetrics and obstetric operations, a knowledge of which, as practically admitted by the defendant himself, is indispensable to the ability to relieve suffering and save life in some of such cases, which are known to be frequent. He says, as hereinbefore quoted: "I do not treat persons for broken limbs, or in cases of obstetrics, etc., that require surgical assistance." Without the requisite learning in obstetrics how would he know a case that needed surgical assistance from one that did not, when sent for to give relief? And if he did not, what would become of his patient while he mistakenly applied his remedy, supposing it was not a case needing surgical assistance, when in fact it was? If the patient dies, is he to be excused because his remedy was a harmless one and did not hurt, when there has been a neglect to use what it is admitted by him would have been an effectual remedy, but which he did not use himself because of a want of knowledge as to how to use it, and did not call in another to use, who did know how, because of a like want of knowledge as to when the conditions were such as to render its use necessary? Without the ability to diagnose disease how would the defendant know a case of pregnancy in certain stages from a case of tumor of the womb? Will each pass away by means of mental suggestion?

These admissions of the defendant, in themselves, prove the wisdom of the law, and the necessity for requiring, as a protection to the people, that the professional healer or curer, who holds himself out to serve the public in that capacity, whatever be his system of treatment, have knowledge of those branches of learning named in the law, to the end that, while leaving him free to choose his own curative means, the public may be assured that the choice shall be made only after an intelligent understanding of the nature of the trouble he offers to treat, and of the human body to which he assumes to minister. The fact that the remedy he adopts is entirely harmless, and might be as effectively used by an uneducated as an educated person, does not, as seen, relieve the danger to the public resulting from entrusting their lives and health to a practitioner of cures who is ignorant of those things a knowledge of which science and experience have demonstrated to be highly useful and beneficial, if not necessary, in any system of treatment.

The law is a police regulation, designed for the protection of the public, and the court is clear in the opinion that the case made against the defendant falls within its terms and spirit, and that the statute is not unconstitutional, at least in so far as this case is concerned. Whether the statute is applicable to one who practices faith or mental cures, not for compensation, but gratuitously out of a sense of religious duty, or whether, if it was intended to so apply, it would be unconstitutional as against such persons because of an infringement of the bill of rights guaranteeing religious freedom, is a question the court need not and does not decide, and on which it expresses no opinion whatever, since that question was not before it.

The Supreme Court of Alabama says, *Ex parte Smith*, 63 *So. R.* 70: We are of the opinion that the agreed statement of facts brought the appellant within the influence of sections 1627 and 7564 of the code of 1907, and the certiorari to review the action of the Court of Appeals is denied.

The defendant also seeks a writ error, as provided by the act of 1911, authorizing a review by this court of the action of the Court of Appeals in upholding the constitutionality of the foregoing sections. We are of the opinion that the Court of Appeals correctly held that the statute was not violative of the federal or state constitutions, in so far as it was applicable to this defendant, who practiced his system of healing for a valuable reward.

Transportation of Sick Persons by Railway Companies

(Central of Georgia Railway Co. vs. Fleming (Ga.), 79 S. E. R. 369)

The Court of Appeals of Georgia reverses a judgment rendered for the plaintiff, who sued the railway company for damages for the alleged negligent homicide of her husband. The petition in substance alleged that he was suffering from appendicitis, and that it was necessary to take him to Atlanta for an operation. The negligence alleged against the defendant, in substance, was the refusal of the conductor to allow the sick man to be taken on the baggage car as a passenger; also that the defendant well knew his condition, and that the failure of the defendant company to provide a safe, convenient and comfortable place for carrying him caused his appendix to burst, and this caused his death. It was alleged that there was no place or room for his cot in the smoking-car, where the conductor directed that he be taken, and that it was necessary to place his cot between two seats thrown together, which caused his body to be placed in a bow-like position, which was uncomfortable and dangerous and which caused the appendix to burst. The court thinks that a general demurrer to the petition should have been sustained and the petition dismissed.

The court holds that, while it is the duty of a carrier of passengers who accepts a sick passenger, to exercise due diligence in taking care of him, and to furnish all practical facilities for his safe and comfortable passage, consistent with the conduct of the carrier's business and the comfort and safety of other passengers, this measure of diligence does not require the carrier to place a sick passenger in its baggage car. It applies only to the transportation of passengers in passenger cars provided for that purpose; and refusal by a conductor of a passenger car to transport a sick passenger in a baggage car raises no liability on the part of the carrier.

The fact that conductors of passenger cars have permitted sick passengers to be placed in the baggage car will not vary the rule, and will not give a passenger the right to be transported in the baggage car. A baggage car is a place of danger, and, either sick or well, a passenger has no right to demand that the company shall transport him as a passenger in the baggage car.

A railroad company is not required by law to carry hospital cars, or cars especially for sick people to ride in. It is not required to convert a baggage car into a car especially for sick people. If it accepts a sick passenger, its duty is to place him in a passenger car in such a position as will insure, so far as possible, his safety and his comfort. Where the carrier does this, the measure of its duty has been fulfilled.

Liability for Performance of Operation on Child at Request of Adult Sister without Consent of Parents—Emergency Operations on Children

(Rishworth and wife vs. Moss and another (Tex.), 159 S. W. R. 122)

The Court of Civil Appeals of Texas reverses a judgment rendered for the defendants in this action brought by the plaintiffs to recover damages because, as they alleged, an operation was performed on their 11-year-old daughter for adenoids, which the plaintiffs had not requested and knew nothing of, until informed that their child had died on the operating-table. The evidence tended to show that the operation was undertaken at the instance and request of an adult sister of the child, and that she was present when chloroform was administered and the operation performed by the defendants The child never recovered consciousness after being anesthetized The court bases its decision on the broad proposition that the mere fact that a child of tender years is taken to a surgeon's office by an elder sister, without the consent of the parents of the child, will not justify an operation on the child It holds that it was clearly error to instruct the jury that if they believed from the evidence that the plaintiff's daughter took the child to Dr Moss for the purpose of being operated on, and believed that the defendants in good faith performed the operation with ordinary care, then verdict must be for the defendants, and this, too, notwithstanding there was no consent from the parents that the operation should be performed

The court says that the right of the child to bind the parent depends, not on any principle peculiar to the relationship of parent and child, but on principles appertaining to the law of agency The relationship can be used only in drawing the inference of agency on slighter facts than as to other parties not so related It follows that if the adult daughter in this instance had any authority to employ a physician to operate on her minor sister, she had that authority, not by reason of her relationship to the child or the parents, but by virtue of an agency, express or implied, from her parents, or at least one of them Her authority must be viewed in the light of the rules and principles of the law of agency, rather than those rules connected with and arising out of domestic relations

All of the cases proceed on the theory that before an operation can be lawfully performed, it must be preceded by the consent of the person capable of consent, or of the person empowered to consent to such operation on the person of one incapable of giving consent

The law, as enunciated by the few courts which have passed thereon, is not so clear and satisfactory as it should be in cases of this character, but it seems to be reasonably established that a physician is liable for operating on a patient unless he obtains the consent of the patient, if competent, and, if not, of some one, who under the circumstances would be legally authorized to give the requisite consent

Of course consent may be presumed from circumstances, without direct proof, but there must be consent in every case, except in an emergency when to delay to obtain consent would endanger the life or health of the patient

A child of tender years being incapable of legally consenting to the administration of an anesthetic and a surgical operation, consent must be obtained from the person clothed with authority to consent by the law, which would be the parent or guardian, in case there be such person

Under the circumstances of this case, the sister, whether adult or otherwise, would have no more authority by virtue of such relationship than would any other person, and it was fundamental error on the part of the court to instruct the jury that the presence of the elder sister, as a matter of law, justified the physicians in performing the operation The parents were easily accessible by telephone or telegraph and there was no emergency

The question of consent of the parents was one of fact to be submitted to the jury, and the issue as to the skill and care that was exercised was one to be submitted in the alternative if consent was given In the absence of consent to the operation the utmost skill and care in its performance would not justify the operation

On a motion for rehearing, which it denies the court says that it thinks it "clear, manifest to the understanding, plain, evident, obvious, appearing to the eye or mind" that it is error to instruct a jury that a minor child, 11 years of age can be operated on by a surgeon, without the consent of the parents, if the child was taken to the surgeon's office by an adult sister. The charge did not place immunity for the physician on the ground of consent of the child itself, nor on the emergency of the occasion, but merely on the proposition that "the daughter of the plaintiffs took the child to Dr. Moss for the purpose of being operated on ' The court holds that such an instruction is absolutely and fundamentally wrong

The court does not wish it understood, however, that it has intimated an indorsement of the proposition that an infant of tender years is given by law any authority or power to judge of the necessity of having a dangerous operation performed on an infant in case of an emergency, without the consent of the parents, cannot be justified on the ground of the consent of such infant but on the ground of the emergency. The physician in an emergency, in which the life of the infant is at stake, is justified in performing an operation without the consent of parent or guardian, not on the ground that the infant can contract for necessaries, but on the ground that the emergency exists, and the question of emergency would be one of fact to be considered by a jury.

If, however, it could be held that an infant could contract for a surgical operation, on the ground that it was necessary. it would always be a question of fact as to whether it was necessary and that the parent or guardian had refused to have it done The law does not give the girl under 15 the power to consent to the use of her person, and it would seem to be a dangerous proposition to authorize children of the age of the dead child to decide whether an operation is necessary, in defiance of the consent of its parents

A married woman's power over her person cannot be classed with that of an infant of tender years over her person, but. even in the case of a married woman. it appears from the case of *State vs Housekeeper*, 70 Md 162, that there must be an emergency, and a failure on the part of the husband to respond to the call of the emergency

(Concluded from page 231)

An Experimental Study of Nerve Regeneration

Dr S Walter Ranson During the last eight years a number of investigators have used the Cajal stain, or some of its modifications, in the study of nerve tissue These studies have brought to light a number of changes which occur in the last few millimeters of the proximal and distal stumps which had been overlooked by other methods of study These changes occurred within a few days, in fact, within the first twenty four or forty eight hours after the operation Within the first twenty four hours the axon undergoes a swelling which is located perhaps 0 2 mm from the cut surface, and the neural fibers of the axon become rearranged in a dense neurofibrillar reticulum Four days after the operation in the last half millimeter of the proximal stump the following changes are seen The medullated fibers show the myelin sheaths completely disintegrated, and the axons have their neurofibrils rearranged in a dense reticulum beneath the neurilemma These changes are entirely transitory phenomena and disappear within fourteen days Quite similar changes occur in the distal stump The early phenomena in neither the proximal nor the distal stump have anything to do with the final regeneration of the nerve By means of the Cajal method we are able to follow clearly the downgrowth of the new axon from the proximal stump

The changes which lead to the final regeneration of the nerve may be summarized under four headings. (1) the formation of nucleated protoplasmic bands from the dead fibers in the distal portion, (2) the branching of the old axon in the proximal stump with the formation in this way of a large number of new fibers, (3) the downgrowth of these new axons from the proximal stump through the scar, and (4) the growth of the new axons through the protoplasmic bands of the distal stump In cross sections it may often be seen that fifty new axons develop from one old one in the proximal stump The part of the scar which immediately underlies the distal stump is free from nerve-fibers excepting in one limited area. The new fibers in the distal stump are everywhere free from axons, excepting in that part which is overlaid by the innervated part of the scar. In these bands in this region one sees sharply defined axons. When the two ends of the nerve have been sutured at the operation, then large numbers of fibers enter the distal stump, and they can be seen in large numbers growing down to protoplasmic bands of the distal stump, so that one can say in summary that the view which was maintained by Waller more than fifty years ago as to nerve regeneration is correct, namely, that it takes place by a downgrowth of new axons from the proximal stump.

Degeneration and Regeneration of the Nervous Elements in Experimental Beriberi

Dr. Elbert Clark: There are two types of beriberi—ship beriberi and atrophic beriberi, each of which has pronounced charactertistics. In both types the disease runs a variable course, two patients rarely giving the same symptom-complex. In ship beriberi there is edema, especially of the feet and legs. The hands, arms and lower abdominal walls show some edema, but to a less extent. Hyperesthesia of the extremities *is usually present, and complete anesthesia of the feet and* lower portion of the legs is not rare in advanced cases. Tenderness and pain in the calf muscles is a very frequent symptom. Motor and sensory symptoms are present. Paralysis of the toes and fingers is frequently encountered. Cardiac disturbances are present, as a rule, with a rapid, somewhat irregular and weak pulse, easily accelerated by the slightest exertion. There may be a reduplication of the second pulmonic sound. In the atrophic variety there is no edema, but great emaciation. Other disturbances present resemble more or less ship beriberi. A great many cases run a less severe course and last many years. The greatest advance in the study of the disease has been along the line of etiology. A great many observers hold that it is a true infectious disease, but others believe that it results from faulty nutrition, and class it as a disease of faulty metabolism. Beriberi occurs most frequently among people whose principal diet is polished rice. Polished rice bears to red rice the same relation as white to graham flour.

According to the theory of auto-intoxication these neurilemma nuclei are capable of producing a new axis cylinder and new myelin sheath, which is capable of conducting sensation. Opponents to this theory hold that it merely serves as a scaffold. In either case the proliferation of nuclei in the neurilemma sheath is supposed to be absolutely necessary. In brief, we apparently have a regeneration of the axis cylinders without participation of the embryonic nerve-fibers and without any assistance from the nucleated neuron sheath. We have found that degeneration in the fowls in which beriberi was produced experimentally is brought about by prolonged feeding of polished rice, and regeneration is brought about by adding meats, grass, etc., to the diet. No evidence of degeneration was observed in the spinal cord.

DISCUSSION

Dr. Judson Herrick: One of the points brought out by Dr. Clark is the functional unity of a neuron. Correlated with that, however, is the problem as to how far the individual parts of the neuron are capable of autogenous activity, in either functional or regenerative fashion. That has been the great problem for many years, which now seems to be well under way to a solution so far as the fundamentals of it are concerned. The phenomena of regeneration, as we know them biologically in other than nerve tissues, have been also the subject of very extensive experiments, and the regenerative phenomena which belong to that class of activity which is called biologic regulation come out clearly, I think, in all of the features which have been described this evening. From the first the neuron which has been subjected to injury, either from a toxin or a lesion, appears to make an effort to restore itself to its normal form. There is a form regulation, and in the process of this restoration the neuron, as a whole, *participates.*

Of these phenomena of biologic regulation after injury there is in the simpler forms a process, first, of redifferentiation of the tissues adjacent to the injury. We are inclined commonly to think of regeneration of these nerve-fibers as following somewhat that same law. There is more or less of redifferentiation throughout the neurons, which may go beyond redifferentiation and result in ultimate destruction. The nuclei of the neurilemma are more resistant than the rest of the fibers. The question is, Are they capable of completing the process of redifferentiation without assistance, or are they not? It seems to me that the data brought forth this evening add the final proof necessary for the decision of that question. They are not capable of completing the process of redifferentiation to a fundamental form. They rarely are able in normal development to come to their perfect form without the cooperation of functional activity during the later stage of the process.

The most striking thing in connection with Dr. Clark's work has been his demonstration of the fact that the whole process may go on without the production of a local lesion. These considerations not only have a bearing on the repair of nerve-fibers which have been injured by toxins as *distinguished from those produced by mechanical injuries, but* also are related to the neuron, as a whole, and from both of these points of view it seems to me that the observations reported are of considerable importance.

Dr. S. Walter Ranson: I want to call attention to one point mentioned by Dr. Clark which is of especial interest, and that is the development of new axons without any proliferation of the neural cells. A good case of confirmatory evidence along the same line is that of an observer who has transplanted the spinal ganglion into a nutritive solution; the ganglion lived in the test-tube, and new fibers have grown out from the old fibers in this medium. These new axons which have grown out into the medium in the test-tube have, of course, been entirely free from contact with any proliferated neurilemma cells. The two pieces of evidence are along the same line.

WESTERN SURGICAL ASSOCIATION

Twenty-Third Annual Meeting, held at St. Louis, Dec. 19-20, 1913

(Continued from page 232)

Pericolic Membranes Resulting from Experimentally Produced Coprostasis

Dr. Joseph Rilus Eastman, Indianapolis: I have experimentally produced pericolic membranes in rabbits by inducing a low-grade plastic peritonitis. The mild adhesive peritonitis occurs as the result of the plugging of the large intestine with its own contents. From my observations it appears that extensive membraniform adhesions may result from extreme coprostasis, and this is exactly as we should expect, for we know that incarceration of hernia and other forms of obstruction of the intestinal lumen, without visible lesion of the intestinal wall and without strangulation, lead to mild peritonitis, fusions and membraniform adhesions. Such pericolic membranes are not different in histology and origin from similar membranes about the uterus and uterine adnexa, all representing reactions of the peritoneum to irritation.

Significance of the Pericolic Membrane (Jackson's Veil)

Dr. Daniel N. Eisendrath and Dr. E. W. Schnoor, Chicago: From our observations during operations, from dissection of cadavers and finally from examination of ten fetuses, we believe that certain conclusions can be drawn. The parietocolic fold of Jonnesco is synonymous with the pericolic membrane. It is a reduplication or fold of peritoneum which is constantly found during fetal or postnatal life. There are two distinct types of pericolic membrane, (1) those which are innocent, and (2) those which may cause mechanical interference with the function of the colon. Each case must be judged on the operative findings, and one is not justified in saying that every pericolic membrane requires interference. The majority are perfect, normal structures. Our examinations of fetal cadavers confirm those of Gray and Anderson, that there is a left parietocolic fold which corresponds in every detail to the same structure on the right side It is a constant finding in the fetus, and no doubt search for it in the future during operations on the left side of the abdomen will confirm these fetal observations

Dr Arthur N Collins, Duluth, Minn I have found a vascular film or veil of greater or less extent in at least 75 or 80 per cent of cases In my experience, covering twenty five or thirty cases, the most frequent location of the veil was on the ascending colon, and next on the cecum the hepatic flexure coming third I believe that the membranous veil is intimately concerned in cases of acute or chronic constipation or stasis in the large bowel By treating the membrane surgically, I have relieved the constipation more often than the pain and tenderness

DISCUSSION

Dr L A Greensfelder, Chicago In sixteen instances I found a Jackson's membrane which was not pathologic I believe that the reason the membrane is sometimes not observed in children is that it is a very fine, frail, web like structure which is apt to be overlooked unless one looks for it accurately and carefully

Dr Leonard Freeman, Denver I found the membrane in twenty four cases I am inclined to agree with Dr Eisendrath that it is more or less of a normal structure, at least in the particular cases in which I have had an opportunity to notice it In but two instances that I saw was I at all convinced that it produced any pathologic disturbance to the bowels In one of these cases the obstruction was very marked

Dr Miles F Porter, Fort Wayne, Ind The mere presence of what seems to be a rather unusual fold in the peritoneal cavity does not necessarily call for an operation of one sort or another on that fold It does not seem to me that from a practical point of view it is important to determine whether these folds are of embryonic or of pathologic origin It is important to determine whether or not they are doing any harm I have seen a number of these cases in which the bands have been released and the obstruction has been relieved, but the patients have been made no better

Dr Van Buren Knott, Sioux City, Iowa More harm than good results from injudicious attempts at handling bands supposed to be responsible for symptoms We should have greater familiarity with this subject in order to know in just what cases we should attempt to liberate or remove the membrane

Dr Thomas C Witherspoon, Butte, Mont One error we frequently make is to attribute too much to the bands Undoubtedly children have these bands, but they do not suffer They are active, they are going about, there is no stasis, and the intensification of the mechanical obstruction by the bands that they experience later as they go into their studies or offices, where their habits are sedentary, is due to the occurrence of cesspooling in the bowel, and then stasis begins

Dr Byron B Davis, Omaha I think that the Jackson membrane is a normal one and is present in a large percentage of cases, that in most cases when it is normally formed it is really a conservative anatomic structure rather than a pathologic one, and that in many instances it serves to fix the ascending colon and to prevent a prolapse which would occur in the absence of this membrane The causes of any pathologic condition in this location are very numerous There may be chronic constipation, or an acute colitis, appendicitis with more or less involvement of the peritoneum, or anything causing a peritoneal irritation or inflammation may cause enough increased vascularization and thickening of this membrane, so that it later would contract in such a manner as to bind down the colon to it, as I have found in a few cases

Dr A A Law, Minneapolis We have found this membrane in fifty cases All of them have been studied fluoroscopically with colonic injection of bismuth and also by means of the stereoscope The findings are practically of no value, except as they show whether or not obstruction is present in the large bowel The large bowel takes so many positions, according to the posture of the patient, that it is of little value Every case of ours had cecal ptosis The cecum was in the pelvis, or went down there when the membrane was released

Dr William T Reynolds, Kansas City, Mo: I have had eleven of these cases, the youngest patient being 6 months old In no instance was there an absence of this membrane on the right side of the colon high up, and in no instance was it absent on the terminal ileum In three cases it was present on the opposite side

Dr A A Kerr Salt Lake City The cases which I have seen have been associated with intestinal stasis or chronic appendicitis

Dr Jabez N Jackson, Kansas City, Mo If one finds a loose, vascularized veil floating over the colon, that has no bands of fibrous tissue in it definitely interfering with the capacity of the intestine somewhere, he should dismiss it from his mind When this membrane interferes mechanically with the capacity of the intestine, it should be divided or stripped off and this should depend on the individual case In some instances a mere slit of an incision is all that is necessary Sometimes the attachments are so multiple that no simple line of incision will do it, and we have practically to strip the restricting membrane off

Dr M L Harris Chicago After these membranes are dealt with the case becomes a medical one and unless properly treated these membranes will recur, if due to a pathologic state in the intestinal wall or to low forms of infection We can produce these conditions in animals experimentally. In my opinion this low infection from intestinal stasis is the underlying factor in this condition

Cholecystitis: Factors that Control Results of Operation

Dr Charles H Mayo, Rochester, Minn The results of operation for cholecystitis are influenced by many conditions besides those in the gall bladder itself Among these are a number of infections within the liver and bile ducts causing changes in the balance of the acidity of the stomach and of the alkalinity of the duodenum, the presence of pyloric spasm and changes in the pancreas Special attention is called to a group of lymph nodes extending along the common and hepatic ducts and on the cystic duct Any case of cholecystitis with sufficient infection to produce symptoms will necessarily affect these lymph nodes In the majority of cases, if these lymph nodes are much enlarged, one will find a lymphedema of the head of the pancreas as well as the infection of the gall bladder An exception is the general swelling of the mesenteric nodes through malignancy or gross abdominal infection The majority of cases of cholecystitis are undoubtedly best relieved by cholecystectomy

Repair of the Common Duct by Means of Transplanted Fascia

Dr Carl B Davis and Dr Dean D Lewis, Chicago We have transplanted free fascia from the abdominal wall to bridge gaps in the common duct and to patch partially severed ducts In all cases the gastrohepatic omentum was destroyed so far as any support was given to the choledochus In one series of cases the common duct was cut across and the ends allowed to retract until they were from ½ to 1 inch apart A strip of fascia was removed from over the rectus muscle, passed beneath the ends of the severed duct and fastened by silk sutures to the proximal portion of the common duct and passed well up on the cystic and hepatic ducts The repair at the distal end was done by fixing the fascia to the duodenum behind the entrance of the distal end of the duct into the intestine The fascia was then folded over to form a tube and two continuous sutures used to make it as water tight as possible, over this the omentum was wrapped as an extra precaution

In the second series of cases the common duct was cut partially across and then slit lengthwise for half an inch A strip of abdominal fascia was placed around the duct and the abdomen closed without drainage In eleven cases it was necessary to close the abdomen without drainage, as the

animals pulled out tubes and gauze in the first twenty four hours In some cases we tried to divert the bile from the field of repair by draining the gall bladder, but lost the animals by extravasation of bile into the abdominal cavity after the tubes had been removed by the dogs Whenever a leak occurred in the region of the flap, the experiment failed This occurred in three cases—two in the first series and one in which the duct was merely slit up Five dogs were lost from infection of the abduct wall

Three dogs lived two months in the first series Two of them when killed showed a patent common duct and stools of normal color The third dog, which lived sixty five days, had a constriction at the duodenal end The bile ducts were distended to an enormous degree The fascia was alive and as resistant as the normal tissues In one animal in which the bile duct had been slit longitudinally, the fascia was sutured too tight at the duodenal end, resulting in marked distention of the gall tracts In this case the fascia was alive and strong enough to retain the bile

SOUTHERN SURGICAL ASSOCIATION

Twenty Sixth Annual Meeting, held at Atlanta, Ga Dec 16 18 1913

(Continued from page 233)

Elements Frequently Overlooked in the Treatment of Exophthalmic Goiter

Dr A. J. Ochsner, Chicago The following features have a distinct bearing on the surgical treatment of exophthalmic goiter the physiologic hyperthyroidism present during pregnancy, puberty, etc , that resulting when persons suffering from goiter living in goiter districts change their residence to other regions, disturbance of the balance between production and consumption of thyroid secretion by some severe sudden physical mental or emotional strain, in a class of patients in whom this balance is usually maintained Planning the operation in relation to the margin of safety in the individual case, bearing in mind the periodicity of exacerbation in hyperthyroidism and its relation to the proper time of operation, the harmfulness of undue operative traumatism, the relation between absorption of wound secretion and postoperative hyperthyroidism, and the uselessness and harmfulness of heart stimulants, thyroid extract and iodin

DISCUSSION

Dr Charles H Mayo, Rochester, Minn It is difficult to control patients after operations for goiter, and sometimes I think it is about as easy to operate again as to try to manage them after operation, because so many of them disregard the rules which we lay down for their after care I have seen many cases that could not be improved by operation

Accidental Injury to the Vena Cava during Nephrectomy

Dr LeGrand Guerry, Columbia, S C , reported three cases in which he had injured the vena cava during nephrectomy, in two the accident being unavoidable In one case the hemorrhage from the torn vena cava was successfully controlled by gauze tamponade In all cases the clamp alone was used to close the injured vessel wall The clamp was unlocked on the seventh day and removed on the eighth day

DISCUSSION

Dr Guy LeRoy Hunner, Baltimore I have never injured the renal vein in kidney surgery I have on one or two occasions had hemorrhage from slipping of the renal artery or vein, and I wish to emphasize a point in dealing with such hemorrhages in a deep hole, especially if the kidney has not yet been removed, namely, that we do not use clamps indiscriminately. The simplest and best method in dealing with these blind hemorrhages is the use of the index finger or better the thumb and finger, if the bleeding is in such a position that we can do that Ordinarily, by catching the bleeding point *immediately*, by thumb and finger pressure we can use gauze points and clean out the wound and have perfect control of the field for clamping or suturing, whichever way seems to be the best for dealing with the bleeding point Some of these injuries occur from the blind use of forceps in a place where nothing can be seen and the real bleeding point is obscured by the fresh bleeding

Dr Hubert A Royster, Raleigh, N C · While doing a nephrectomy through an anterior incision, in lifting up the kidney, I tore the vena cava With clamps it was held until I put on a double mattress suture and controlled it, and then grasped the renal vein and cared for it This accident is less liable to happen during intracapsular nephrectomy than if one goes to the outside, because we cannot go quite so far down when we cut through the capsule and reflect it

Dr I S Stone, Washington, D C · I have had two accidents, one to the axillary vein and one to the renal vein, both having been partially torn In one case I attempted to suture the vena cava by drawing the vein over and covering in the defect, but I was afraid there would be continued hemorrhage I found it comparatively easy, after the sutures were drawn together, by diminishing the size of the vessel one half, to put a ligature around the whole mass, which entirely occluded it, brought all the parts together, and stopped the hemorrhage Both patients recovered without the least difficulty

Dr Gordon K. Dickinson, Jersey City, N J In removing a hypernephroma I went into the vena cava, but found that very little finger pressure controlled it

Dr J M T. Finney, *Baltimore*· *When I was one of the* house officers in the Massachusetts General Hospital, I assisted Dr Cabot in a case in which the patient had been operated on previously for fibroid At that operation, which was done by another operator, one of the ureters had been cut, leaving a urinary fistula, and for the relief of the fistula the second operation was being performed by Dr. Cabot It developed subsequently at the necropsy that this patient had an abnormally short renal vein and when the kidney was ligated the ligature had included the lateral wall of the vena cava When the pedicle was cut, the wall being inverted there was within a few moments after the kidney had been removed a gush of blood such as I had never seen before, have never seen since, and hope never to see again Dr. Cabot instantly attempted to pick up the bleeding point with a pair of forceps, and succeeded after a little while, and after cleaning out the wound found he had clamped the full caliber of the vena cava. At that time, which was many years ago, it was deemed best not to attempt to do more than leave on the clamp The patient had lost so much blood that she died in a very few minutes I mention this case as an illustration of the fact that this accident is really a serious one

Dr Francis Reder, St Louis I had the misfortune to tear the vena cava, but it taught me a lesson In operating now, as soon as I get down to dangerous territory, I introduce a ligature, double thread it with needle, one in the lower pole of the kidney and one in the upper pole, I clamp my way along, keep on sewing, and with gentle traction on the thread I know when I am down near the vena cava, but by applying delicate pointed clamps, with double threaded ligature, throwing the tissues over the clamp, I can finish my operation without ligating separately the renal veins, and with very little loss of blood

Dr Francis R Hagner, Baltimore I have had two cases in which the vein close to the vena cava slipped out of the forceps The first thing is to get the kidney out as soon as possible, the operator can see what he is doing to better advantage, and can better apply the clamps Venous bleeding is difficult to control, but there is very little or no trouble in controlling arterial bleeding

Ultimate Results in Eight Cases of Colectomy for Fecal Stasis

Dr John G Clark, Philadelphia, reported eight cases, five patients relieved of constipation, three cases were a distinct success, one patient died from postoperative adhesions, one was reoperated on subsequently for the relief of a blind pouch, and another will probably have to be operated on for a similar condition This operation is not an operation for constipation. It is only an operation for segmental obstruction

Artificial Vagina by Intestinal Transplantation

Dr H J Boldt, New York I have had two cases of formation of an artificial vagina by intestinal transplantation It is the only method that has given satisfactory results Other methods I have used were eventually always failures In both of these cases there was a complete congenital absence of the vagina, and in each case the ileum was used

DISCUSSION

Dr Thomas S Cullen, Baltimore I have had several cases in which the pelvic organs were present but the vagina had not been opened, and it was necessary to go up and find the vaginal mucosa and attach it to the skin These cases have been in girls between 15 and 18 years of age In one case in which the patient had no vagina at all, I attempted to make an opening between the rectum and bladder With one finger in the rectum and with artery forceps in the bladder I worked through the septum from above I felt a mass on the right side and came to the conclusion that it was the uterus There was an accumulation there Three or four inches in I felt that this was hard I immediately opened the abdomen and found that the mass in the right side was a unilateral kidney The tube and ovary were present on the right side The tube was visible The fimbriated end was sticking out through the hernial ring, the ovary was covered over by peritoneum and the round ligament came down and formed a loop and went back On the opposite side there was nothing to be seen, but outside the pelvis I could feel the ovary and tube

Adenomyoma of the Rectovaginal Septum

Dr Thomas S Cullen, Baltimore These growths have the same histologic picture as adenomyoma of the uterus They consist of typical uterine glands lying in their characteristic stroma and surrounded by diffuse myomatous tissue They evidently start in the lower part of the uterus and then spread out in the rectovaginal septum These growths, which in the beginning may be readily shelled out later become so fixed to the rectum that it is necessary to take away a portion of the bowel with the tumor

These growths can easily be differentiated clinically from cancer of the rectum Adenomyomas of the rectovaginal septum invade the bowel from without. They may extend into and narrow the bowel lumen, but the overlying rectal mucosa is still intact The only rectal symptoms that one may expect are those due to partial constriction of the bowel Cancer of the bowel, on the other hand, starts in the mucosa and extends outward It is usually accompanied by hemorrhage from the bowel and later by the fetid discharge due to breaking down of the cancerous tissue With adenomyoma of the rectovaginal septum there is usually no bleeding On proctoscopic examination in the one case the cancerous area can readily be seen, in the other while the bowel is narrowed the mucosa is nevertheless everywhere intact

While these growths are histologically benign and while they naturally never give rise to metastasis, nevertheless, if portions of the growth be left they continue to grow as a result of the adhesions, and alarming and in fact fatal obstructive symptoms may develop

Use of the Paquelin Cautery in Cervicitis, with Special Reference to Its Value in Sterility

Dr Guy L Hunner, Baltimore I now have a series of 241 cases treated with the cautery with practically universal success I wish to warn against the use of the cautery in the acute or subacute stages of gonorrhea, and also against losing valuable time by using the cautery in an early case of epithelioma of the cervix Any suspicious case that cannot be diagnosed grossly should have a specimen removed for microscopic examination In the chronic inflammatory cases in which a portion of the leukorrhea comes from a metritis or endometritis, the cervical treatment should cease when the cervix has a normal appearance and the cautery fails to empty more retention glands, although there will still persist some leukorrhea from within the uterus Other pathologic conditions for which the cautery has been found useful are urethral caruncle, polypus of the cervix, fibroma of the vaginal wall, retention cysts and abscesses of Skene's and Bartholin's glands

In sterility cases, fourteen patients became pregnant after the use of the cautery Some of these patients had not been married long enough to be classed as sterile, others had borne children and were probably only temporarily sterile, and others had reposition of the pelvic organs with placement of a pessary treatment that might have resulted in pregnancy without the use of the cautery It is more than probable that in six the pregnancy followed as a consequence of using the cautery Eight cases were failures

DISCUSSION

Dr Henry T Byford, Chicago With reference to the use of the Paquelin cautery in cases of sterility, it seems to me it is irrational in that we substitute a pathologic cervix for a normal one in which carcinoma is likely to occur. If we dilate the cervix and keep it widely dilated we give the patient a chance to become pregnant

Dr Herman J Boldt, New York What is the risk of getting subsequent atresia of the cervical canal from the use of the Paquelin cautery?

Dr George H Noble, Atlanta, Ga Instead of using the cautery in these cases I make six incisions, on either side, two anteriorly and two posteriorly This gives me ¼ inch between the incisions cutting clear through the mucous membrane and up to the internal os, pushing it well up into the internal os The effect of the cautery, I am satisfied, is deeper than the cut of the knife The result is, that with healthy mucous membrane, stenosis does not result In cauterizing, the mucous membrane is destroyed, but there is a healthy strip left between each incision The effect of the heat traverses the area underneath and either sterilizes the glands or destroys them

Dr I S Stone, Washington, D C If we are going to take three or five months to cure a patient of chronic cervical endometritis, some other method of treatment should be adopted If we wish to destroy the glands, why not split the cervix wide open and cut away the glands? Let us destroy the cervical tissue at once, leave a strip of undenuded tissue which has been curetted, bring back the cervix and sew it up If that is done, the cervix will be as elastic as any cervix after a trachelorrhaphy It will be free from cicatricial tissue which would interfere with pregnancy or delivery

Dr Henry O Marcy, Boston The Paquelin cautery has its place in the treatment of these conditions, and I have used it with excellent results

Dr Guy L Hunner, Baltimore The possibility of stenosis after the use of the cautery is more imaginary than real At first I thought that it would occur, but experience shows that it does not

Treatment of Vesical Fistulas at the Vaginal Vault Following Surgical Operations

Dr Howard A. Kelly, Baltimore I have discovered an excellent plan of operating in cases which obviates all difficulties and dangers, simplifies the treatment and, I believe gives a maximum certainty of cure The patient lies in the lithotomy posture, with the posterior vaginal wall well retracted If necessary a paravaginal incision is made to expose the vault and the fistula When the operator cuts transversely just above or through the scar tissue and carefully opens the peritoneal cavity continuing the incision from side to side until it is as big as in a vaginal hysterectomy This must be done without injuring the bladder or affecting the fistulous tract in any way A good plan now is to incise the tissues longitudinally through the fistula down to the bladder, which is dissected away from the vagina and sewed up separately, while the vagina is united over the vesical wound, if the operator prefers it at a right angle to it so that the two lines of suturing cross each other. I usually

animals pulled out tubes and gauze in the first twenty four hours In some cases we tried to divert the bile from the field of repair by draining the gall bladder, but lost the animals by extravasation of bile into the abdominal cavity after the tubes had been removed by the dogs Whenever a leak occurred in the region of the flap, the experiment failed This occurred in three cases—two in the first series and one in which the duct was merely slit up Five dogs were lost from infection of the abduct wall

Three dogs lived two months in the first series Two of them when killed showed a patent common duct and stools of normal color The third dog, which lived sixty five days, had a constriction at the duodenal end The bile ducts were distended to an enormous degree The fascia was alive and as resistant as the normal tissues In one animal in which the bile duct had been slit longitudinally, the fascia was sutured too tight at the duodenal end, resulting in marked distention of the gall tracts In this case the fascia was alive and strong enough to retain the bile

Elements Frequently Overlooked in the Treatment of Exophthalmic Goiter

Dr A. J. Ochsner, Chicago The following features have a distinct bearing on the surgical treatment of exophthalmic goiter the physiologic hyperthyroidism present during pregnancy, puberty, etc , that resulting when persons suffering from goiter living in goiter districts change their residence to other regions, disturbance of the balance between production and consumption of thyroid secretion by some severe sudden physical mental or emotional strain, in a class of patients in whom this balance is usually maintained Planning the operation in relation to the margin of safety in the individual case, bearing in mind the periodicity of exacerbation in hyperthyroidism and its relation to the proper time of operation, the harmfulness of undue operative traumatism, the relation between absorption of wound secretion and postoperative hyperthyroidism, and the uselessness and harmfulness of heart stimulants, thyroid extract and iodin

DISCUSSION

Dr Charles H Mayo, Rochester, Minn It is difficult to control patients after operations for goiter, and sometimes I think it is about as easy to operate again as to try to manage them after operation, because so many of them disregard the rules which we lay down for their after care I have seen many cases that could not be improved by operation

Accidental Injury to the Vena Cava during Nephrectomy

Dr LeGrand Guerry, Columbia, S C , reported three cases in which he had injured the vena cava during nephrectomy, in two the accident being unavoidable In one case the hemorrhage from the torn vena cava was successfully controlled by gauze tamponade In all cases the clamp alone was used to close the injured vessel wall The clamp was unlocked on the *seventh day and* removed on the eighth day

DISCUSSION

Dr Guy LeRoy Hunner, Baltimore I have never injured the renal vein in kidney surgery I have on one or two occasions had hemorrhage from slipping of the renal artery or vein, and I wish to emphasize a point in dealing with such hemorrhages in a deep hole, especially if the kidney has not yet been removed, namely, that we do not use clamps indiscriminately. The simplest and best method in dealing with these blind hemorrhages is the use of the index finger or better the thumb and finger, if the bleeding is in such a position that we can do that Ordinarily, by catching the bleeding point immediately, by thumb and finger pressure we can use gauze points and clean out the wound and have perfect control of the field for clamping or suturing, whichever way seems to be the best for dealing with the bleeding point Some of these injuries occur from the blind use of forceps in a place where nothing can be seen and the real bleeding point is obscured by the fresh bleeding

Dr Hubert A Royster, Raleigh, N C While doing a nephrectomy through an anterior incision, in lifting up the kidney, I tore the vena cava With clamps it was held until I put *on a* double *mattress suture and controlled* it, and then grasped the renal vein and cared for it This accident is less liable to happen during intracapsular nephrectomy *than if one goes to the outside, because we cannot go* quite so far down when we cut through the capsule and reflect it

Dr I S Stone, Washington, D C I have had two accidents, one to the axillary vein and one to the renal vein, both having been partially torn In one case I attempted to suture the vena cava by drawing the vein over and covering in the defect, but I was afraid there would be continued hemorrhage I found it comparatively easy, after the sutures were drawn together, by diminishing the size of the vessel one half, to put a ligature around the whole mass, which entirely occluded it, brought all the parts together, and stopped the hemorrhage Both patients recovered without the least difficulty

Dr Gordon K. Dickinson, Jersey City, N J In removing a hypernephroma I went into the vena cava, but found that very little finger pressure controlled it

Dr J M T. Finney, Baltimore When I was one of the house officers in the Massachusetts General Hospital, I assisted Dr Cabot in a case in which the patient had been operated on previously for fibroid At that operation, which was done by another operator, one of the ureters had been cut, leaving a urinary fistula, and for the relief of the fistula the second operation was being performed by Dr. Cabot It developed subsequently at the necropsy that this patient had an abnormally short renal vein, and when the kidney was ligated the ligature had included the lateral wall of the vena cava When the pedicle was cut, the wall being inverted, there was within a few moments after the kidney had been removed a gush *of blood such as I had never seen before,* have never seen since, and hope never to see again Dr Cabot instantly attempted to pick up the bleeding point with a pair of forceps, and succeeded after a little while, and after cleaning out the wound found he had clamped the full caliber of the vena cava At that time, which was many years ago, it was deemed best not to attempt to do more than leave on the clamp The patient had lost so much blood that she died in a very few minutes I mention this case as an illustration of the fact that this accident is really a serious one

Dr Francis Reder, St Louis I had the misfortune to tear the vena cava, but it taught me a lesson In operating now, as soon as I get down to dangerous territory, I introduce a ligature, double thread it with needle, one in the lower pole of the kidney and one in the upper pole, I clamp my way along, keep on sewing, and with gentle traction on the thread I know when I am down near the vena cava, but by applying delicate pointed clamps, with double threaded ligature, throwing the tissues over the clamp, I can finish my operation without ligating separately the renal veins, and with very little loss of blood

Dr Francis R Hagner, Baltimore I have had two cases in which the vein close to the vena cava slipped out of the forceps The first thing is to get the kidney out as soon as possible, the operator can see what he is doing to better advantage, and can better apply the clamps Venous bleeding is difficult to control, but there is very little or no trouble in controlling arterial bleeding

Ultimate Results in Eight Cases of Colectomy for Fecal Stasis

Dr John G Clark, Philadelphia, reported eight cases, five patients relieved of constipation, three cases were a distinct success, one patient died from postoperative adhesions, one was reoperated on subsequently for the relief of a blind pouch, and another will probably have to be operated on for a similar condition. This operation is not an operation for constipation. It is only an operation for segmental obstruction.

Artificial Vagina by Intestinal Transplantation

Dr. H. J. Boldt, New York: I have had two cases of formation of an artificial vagina by intestinal transplantation. It is the only method that has given satisfactory results. Other methods I have used were eventually always failures. In both of these cases there was a complete congenital absence of the vagina, and in each case the ileum was used.

DISCUSSION

Dr. Thomas S. Cullen, Baltimore: I have had several cases in which the pelvic organs were present but the vagina had not been opened, and it was necessary to go up and find the vaginal mucosa and attach it to the skin. These cases have been in girls between 15 and 18 years of age. In one case in which the patient had no vagina at all, I attempted to make an opening between the rectum and bladder. With one finger in the rectum and with artery forceps in the bladder I worked through the septum from above. I felt a mass on the right side and came to the conclusion that it was the uterus. There was an accumulation there. Three or four inches in I felt that this was hard. I immediately opened the abdomen and found that the mass in the right side was a unilateral kidney. The tube and ovary were present on the right side. The tube was visible. The fimbriated end was sticking out through the hernial ring; the ovary was covered over by peritoneum and the round ligament came down and formed a loop and went back. On the opposite side there was nothing to be seen, but outside the pelvis I could feel the ovary and tube.

Adenomyoma of the Rectovaginal Septum

Dr. Thomas S. Cullen, Baltimore: These growths have the same histologic picture as adenomyoma of the uterus. They consist of typical uterine glands lying in their characteristic stroma and surrounded by diffuse myomatous tissue. They evidently start in the lower part of the uterus and then spread out in the rectovaginal septum. These growths, which in the beginning may be readily shelled out, later become so fixed to the rectum that it is necessary to take away a portion of the bowel with the tumor.

These growths can easily be differentiated clinically from cancer of the rectum. Adenomyomas of the rectovaginal septum invade the bowel from without. They may extend into and narrow the bowel lumen, but the overlying rectal mucosa is still intact. The only rectal symptoms that one may expect are those due to partial constriction of the bowel. Cancer of the bowel, on the other hand, starts in the mucosa and extends outward. It is usually accompanied by hemorrhage from the bowel and later by the fetid discharge due to breaking down of the cancerous tissue. With adenomyoma of the rectovaginal septum there is usually no bleeding. On rectoscopic examination in the one case the cancerous area can readily be seen, in the other while the bowel is narrowed the mucosa is nevertheless everywhere intact.

While these growths are histologically benign and while they naturally never give rise to metastasis, nevertheless, if portions of the growth be left they continue to grow as a result of the adhesions, and alarming and in fact fatal obstructive symptoms may develop.

Use of the Paquelin Cautery in Cervicitis, with Special Reference to Its Value in Sterility

Dr. Guy L. Hunner, Baltimore: I now have a series of 241 cases treated with the cautery with practically universal success. I wish to warn against the use of the cautery in the acute or subacute stages of gonorrhea, and also against losing valuable time by using the cautery in an early case of epithelioma of the cervix. Any suspicious case that cannot be diagnosed grossly should have a specimen removed for microscopic examination. In the chronic inflammatory cases in which a portion of the leukorrhea comes from a metritis or endometritis, the cervical treatment should cease when the cervix has a normal appearance and the cautery fails to empty more retention glands, although there will still persist some leukorrhea from within the uterus. Other pathologic conditions for which the cautery has been found useful are urethral caruncle, polypus of the cervix, fibroma of the vaginal wall, retention cysts and abscesses of Skene's and Bartholin's glands.

In sterility cases, fourteen patients became pregnant after the use of the cautery. Some of these patients had not been married long enough to be classed as sterile; others had borne children and were probably only temporarily sterile, and others had reposition of the pelvic organs with placement of a pessary treatment that might have resulted in pregnancy without the use of the cautery. It is more than probable that in six the pregnancy followed as a consequence of using the cautery. Eight cases were failures.

DISCUSSION

Dr. Henry T. Byford, Chicago: With reference to the use of the Paquelin cautery in cases of sterility, it seems to me it is irrational in that we substitute a pathologic cervix for a normal one in which carcinoma is likely to occur. If we dilate the cervix and keep it widely dilated we give the patient a chance to become pregnant.

Dr. Herman J. Boldt, New York: What is the risk of getting subsequent atresia of the cervical canal from the use of the Paquelin cautery?

Dr. George H. Noble, Atlanta, Ga.: Instead of using the cautery in these cases I make six incisions, on either side, two anteriorly and two posteriorly. This gives me ¼ inch between the incisions cutting clear through the mucous membrane and up to the internal os, pushing it well up into the internal os. The effect of the cautery, I am satisfied, is deeper than the cut of the knife. The result is, that with healthy mucous membrane, stenosis does not result. In cauterizing, the mucous membrane is destroyed, but there is a healthy strip left between each incision. The effect of the heat traverses the area underneath and either sterilizes the glands or destroys them.

Dr. I. S. Stone, Washington, D. C.: If we are going to take three or five months to cure a patient of chronic cervical endometritis, some other method of treatment should be adopted. If we wish to destroy the glands, why not split the cervix wide open and cut away the glands? Let us destroy the cervical tissue at once, leave a strip of undenuded tissue which has been curetted, bring back the cervix and sew it up. If that is done, the cervix will be as elastic as any cervix after a trachelorrhaphy. It will be free from cicatricial tissue which would interfere with pregnancy or delivery.

Dr. Henry O. Marcy, Boston: The Paquelin cautery has its place in the treatment of these conditions, and I have used it with excellent results.

Dr. Guy L. Hunner, Baltimore: The possibility of stenosis after the use of the cautery is more imaginary than real. At first I thought that it would occur, but experience shows that it does not.

Treatment of Vesical Fistulas at the Vaginal Vault Following Surgical Operations

Dr. Howard A. Kelly, Baltimore: I have discovered an excellent plan of operating in cases which obviates all difficulties and dangers, simplifies the treatment and, I believe, gives a maximum certainty of cure. The patient lies in the lithotomy posture, with the posterior vaginal wall well retracted. If necessary a paravaginal incision is made to expose the vault and the fistula. When the operator cuts transversely just above or through the scar tissue and carefully opens the peritoneal cavity continuing the incision from side to side until it is as big as in a vaginal hysterectomy. This must be done without injuring the bladder or affecting the fistulous tract in any way. A good plan now is to incise the tissues longitudinally through the fistula down to the bladder, which is dissected away from the vagina and sewed up separately, while the vagina is united over the vesical wound, if the operator prefers it at a right angle to it so that the two lines of suturing cross each other. I usually

animals pulled out tubes and gauze in the first twenty four hours In some cases we tried to divert the bile from the field of repair by draining the gall bladder, but lost the animals by extravasation of bile into the abdominal cavity after the tubes had been removed by the dogs Whenever a leak occurred in the region of the flap, the experiment failed This occurred in three cases—two in the first series and one in which the duct was merely slit up Five dogs were lost from infection of the abduct wall

Three dogs lived two months in the first series Two of them when killed showed a patent common duct and stools of normal color The third dog, which lived sixty five days, had a constriction at the duodenal end The bile ducts were distended to an enormous degree The fascia was alive and as resistant as the normal tissues In one animal in which the bile duct had been slit longitudinally, the fascia was sutured too tight at the duodenal end, resulting in marked distention of the gall tracts In this case the fascia was alive and strong enough to retain the bile

Twenty Sixth Annual Meeting, held at Atlanta, Ga, Dec 16 18 1913

(Continued from page 233)

Elements Frequently Overlooked in the Treatment of Exophthalmic Goiter

Dr A J. Ochsner, Chicago The following features have a distinct bearing on the surgical treatment of exophthalmic goiter the physiologic hyperthyroidism present during pregnancy, puberty, etc, that resulting when persons suffering from goiter living in goiter districts change their residence to other regions, disturbance of the balance between production and consumption of thyroid secretion by some severe sudden physical mental or emotional strain, in a class of patients in whom this balance is usually maintained Planning the operation in relation to the margin of safety in the individual case, bearing in mind the periodicity of exacerbation in hyperthyroidism and its relation to the proper time of operation, the harmfulness of undue operative traumatism, the relation between absorption of wound secretion and postoperative hyperthyroidism, and the uselessness and harmfulness of heart stimulants, thyroid extract and iodin

DISCUSSION

Dr Charles H Mayo, Rochester, Minn It is difficult to control patients after operations for goiter, and sometimes I think it is about as easy to operate again as to try to manage them after operation, because so many of them disregard the rules which we lay down for their after care I have seen many cases that could not be improved by operation

Accidental Injury to the Vena Cava during Nephrectomy

Dr LeGrand Guerry, Columbia, S C, reported three cases in which he had injured the vena cava during nephrectomy, in two the accident being unavoidable In one case the hemorrhage from the torn vena cava was successfully controlled by gauze tamponade In all cases the clamp alone was used to close the injured vessel wall The clamp was unlocked on the seventh day and removed on the eighth day

DISCUSSION

Dr Guy LeRoy Hunner, Baltimore I have never injured the renal vein in kidney surgery I have on one or two occasions had hemorrhage from slipping of the renal artery or vein, and I wish to emphasize a point in dealing with such hemorrhages in a deep hole, especially if the kidney has not yet been removed, namely, that we do not use clamps indiscriminately. The simplest and best method in dealing with these blind hemorrhages is the use of the index finger or better the thumb and finger, if the bleeding is in such a position that we can do that Ordinarily, by catching the bleeding point immediately, by thumb and finger pressure we can use gauze points and clean out the wound and have perfect control of the field for clamping or suturing, whichever way seems to be the best for dealing with the bleeding point Some of these injuries occur from the blind use of forceps in a place where nothing can be seen and the real bleeding point is obscured by the fresh bleeding

Dr Hubert A Royster, Raleigh, N C While doing a nephrectomy through an anterior incision, in lifting up the kidney, I tore the vena cava With clamps it was held until I put on a double mattress suture and controlled it, and then grasped the renal vein and cared for it This accident is less liable to happen during intracapsular nephrectomy than if one goes to the outside, because we cannot go quite so far down when we cut through the capsule and reflect it

Dr I S Stone, Washington, D C I have had two accidents, one to the axillary vein and one to the renal vein, both having been partially torn In one case I attempted to suture the vena cava by drawing the vein over and covering in the defect, but I was afraid there would be continued hemorrhage I found it comparatively easy, after the sutures were drawn together, by diminishing the size of the vessel one half, to put a ligature around the whole mass, which entirely occluded it, brought all the parts together, and stopped the hemorrhage Both patients recovered without the least difficulty

Dr Gordon K. Dickinson, Jersey City, N J In removing a hypernephroma I went into the vena cava, but found that very little finger pressure controlled it

Dr J M T Finney, Baltimore When I was one of the house officers in the Massachusetts General Hospital, I assisted Dr Cabot in a case in which the patient had been operated on previously for fibroid At that operation, which was done by another operator, one of the ureters had been cut, leaving a urinary fistula, and for the relief of the fistula the second operation was being performed by Dr. Cabot It developed subsequently at the necropsy that this patient had an abnormally short renal vein, and when the kidney was ligated the ligature had included the lateral wall of the vena cava When the pedicle was cut, the wall being inverted, there was within a few moments after the kidney had been removed a gush of blood such as I had never seen before, have never seen since, and hope never to see again Dr Cabot instantly attempted to pick up the bleeding point with a pair of forceps, and succeeded after a little while, and after cleaning out the wound found he had clamped the full caliber of the vena cava At that time, which was many years ago, it was deemed best not to attempt to do more than leave on the clamp The patient had lost so much blood that she died in a very few minutes I mention this case as an illustration of the fact that this accident is really a serious one

Dr Francis Reder, St Louis I had the misfortune to tear the vena cava, but it taught me a lesson In operating now, as soon as I get down to dangerous territory, I introduce a ligature, double thread it with needle, one in the lower pole of the kidney and one in the upper pole, I clamp my way along, keep on sewing, and with gentle traction on the thread I know when I am down near the vena cava, but by applying delicate pointed clamps, with double threaded ligature, throwing the tissues over the clamp, I can finish my operation without ligating separately the renal veins, and with very little loss of blood

Dr Francis R Hagner, Baltimore I have had two cases in which the vein close to the vena cava slipped out of the forceps The first thing is to get the kidney out as soon as possible, the operator can see what he is doing to better advantage, and can better apply the clamps Venous bleeding is difficult to control, but there is very little or no trouble in controlling arterial bleeding

Ultimate Results in Eight Cases of Colectomy for Fecal Stasis

Dr John G Clark, Philadelphia, reported eight cases five patients relieved of constipation, three cases were a distinct success, one patient died from postoperative adhesions, one was reoperated on subsequently for the relief of a blind pouch, and another will probably have to be operated on for a similar condition. This operation is not an operation for constipation. It is only an operation for segmental obstruction.

Artificial Vagina by Intestinal Transplantation

Dr. H. J. Boldt, New York: I have had two cases of formation of an artificial vagina by intestinal transplantation. It is the only method that has given satisfactory results. Other methods I have used were eventually always failures. In both of these cases there was a complete congenital absence of the vagina, and in each case the ileum was used.

DISCUSSION

Dr. Thomas S. Cullen, Baltimore: I have had several cases in which the pelvic organs were present but the vagina had not been opened, and it was necessary to go up and find the vaginal mucosa and attach it to the skin. These cases have been in girls between 15 and 18 years of age. In one case in which the patient had no vagina at all, I attempted to make an opening between the rectum and bladder. With one finger in the rectum and with artery forceps in the bladder I worked through the septum from above. I felt a mass on the right side and came to the conclusion that it was the uterus. There was an accumulation there. Three or four inches in I felt that this was hard. I immediately opened the abdomen and found that the mass in the right side was a unilateral kidney. The tube and ovary were present on the right side. The tube was visible. The fimbriated end was sticking out through the hernial ring; the ovary was covered over by peritoneum and the round ligament came down and formed a loop and went back. On the opposite side there was nothing to be seen, but outside the pelvis I could feel the ovary and tube.

Adenomyoma of the Rectovaginal Septum

Dr. Thomas S. Cullen, Baltimore: These growths have the same histologic picture as adenomyoma of the uterus. They consist of typical uterine glands lying in their characteristic stroma and surrounded by diffuse myomatous tissue. They evidently start in the lower part of the uterus and then spread out in the rectovaginal septum. These growths, which in the beginning may be readily shelled out, later become so fixed to the rectum that it is necessary to take away a portion of the bowel with the tumor.

These growths can easily be differentiated clinically from cancer of the rectum. Adenomyomas of the rectovaginal septum invade the bowel from without. They may extend into and narrow the bowel lumen, but the overlying rectal mucosa is still intact. The only rectal symptoms that one may expect are those due to partial constriction of the bowel. Cancer of the bowel, on the other hand, starts in the mucosa and extends outward. It is usually accompanied by hemorrhage from the bowel and later by the fetid discharge due to breaking down of the cancerous tissue. With adenomyoma of the rectovaginal septum there is usually no bleeding. On rectoscopic examination in the one case the cancerous area can readily be seen, in the other while the bowel is narrowed the mucosa is nevertheless everywhere intact.

While these growths are histologically benign and while they naturally never give rise to metastasis, nevertheless, if portions of the growth be left they continue to grow as a result of the adhesions, and alarming and in fact fatal obstructive symptoms may develop.

Use of the Paquelin Cautery in Cervicitis, with Special Reference to Its Value in Sterility

Dr. Guy L. Hunner, Baltimore: I now have a series of 241 cases treated with the cautery with practically universal success. I wish to warn against the use of the cautery in the acute or subacute stages of gonorrhea, and also against losing valuable time by using the cautery in an early case of epithelioma of the cervix. Any suspicious case that cannot be diagnosed grossly should have a specimen removed for microscopic examination. In the chronic inflammatory cases in which a portion of the leukorrhea comes from a metritis or endometritis, the cervical treatment should cease when the cervix has a normal appearance and the cautery fails to empty more retention glands, although there will still persist some leukorrhea from within the uterus. Other pathologic conditions for which the cautery has been found useful are urethral caruncle, polypus of the cervix, fibroma of the vaginal wall, retention cysts and abscesses of Skene's and Bartholin's glands.

In sterility cases, fourteen patients became pregnant after the use of the cautery. Some of these patients had not been married long enough to be classed as sterile; others had borne children and were probably only temporarily sterile, and others had reposition of the pelvic organs with placement of a pessary treatment that might have resulted in pregnancy without the use of the cautery. It is more than probable that in six the pregnancy followed as a consequence of using the cautery. Eight cases were failures.

DISCUSSION

Dr. Henry T. Byford, Chicago: With reference to the use of the Paquelin cautery in cases of sterility, it seems to me it is irrational in that we substitute a pathologic cervix for a normal one in which carcinoma is likely to occur. If we dilate the cervix and keep it widely dilated we give the patient a chance to become pregnant.

Dr. Herman J. Boldt, New York: What is the risk of getting subsequent atresia of the cervical canal from the use of the Paquelin cautery?

Dr. George H. Noble, Atlanta, Ga.: Instead of using the cautery in these cases I make six incisions, on either side, two anteriorly and two posteriorly. This gives me ¼ inch between the incisions cutting clear through the mucous membrane and up to the internal os, pushing it well up into the internal os. The effect of the cautery, I am satisfied, is deeper than the cut of the knife. The result is, that with healthy mucous membrane, stenosis does not result. In cauterizing, the mucous membrane is destroyed, but there is a healthy strip left between each incision. The effect of the heat traverses the area underneath and either sterilizes the glands or destroys them.

Dr. I. S. Stone, Washington, D. C.: If we are going to take three or five months to cure a patient of chronic cervical endometritis, some other method of treatment should be adopted. If we wish to destroy the glands, why not split the cervix wide open and cut away the glands? Let us destroy the cervical tissue at once, leave a strip of undenuded tissue which has been curetted, bring back the cervix and sew it up. If that is done, the cervix will be as elastic as any cervix after a trachelorrhaphy. It will be free from cicatricial tissue which would interfere with pregnancy or delivery.

Dr. Henry O. Marcy, Boston: The Paquelin cautery has its place in the treatment of these conditions, and I have used it with excellent results.

Dr. Guy L. Hunner, Baltimore: The possibility of stenosis after the use of the cautery is more imaginary than real. At first I thought that it would occur, but experience shows that it does not.

Treatment of Vesical Fistulas at the Vaginal Vault Following Surgical Operations

Dr. Howard A. Kelly, Baltimore: I have discovered an excellent plan of operating in cases which obviates all difficulties and dangers, simplifies the treatment and, I believe, gives a maximum certainty of cure. The patient lies in the lithotomy posture, with the posterior vaginal wall well retracted. If necessary a paravaginal incision is made to expose the vault and the fistula. When the operator cuts transversely just above or through the scar tissue and carefully opens the peritoneal cavity continuing the incision from side to side until it is as big as in a vaginal hysterectomy. This must be done without injuring the bladder or affecting the fistulous tract in any way. A good plan now is to incise the tissues longitudinally through the fistula down to the bladder, which is dissected away from the vagina and sewed up separately, while the vagina is united over the vesical wound, if the operator prefers it at a right angle to it so that the two lines of suturing cross each other. I usually provide for drainage. I have in some cases left a considerable part of the vesical peritoneum in the vagina, forming a new vaginal vault. A mushroom catheter is put into the bladder for a few days to keep it at rest during the first part of the healing process, and the patient remains in bed from eight to twelve days, the peritoneal drain being removed in from four to six days.

Resection of the Rectum for Cancer with Preservation of the Sphincter

Dr. Charles H. Mayo, Rochester, Minn.: Extirpation of the cecum and ascending colon for cancer has given a high percentage of cures because an anastomosis of the ileum into the colon was an ideal enterostomy for delivering semiliquids. The two-stage Mikulicz method is one of the safest known, although convalescence is protracted. A permanent colostomy, though abhorrent to all patients, undoubtedly gives a higher percentage of cures than do methods which restore function. I advise thorough abdominal exploration, a temporary or permanent colostomy in the majority of cases, increasing the lumen of the anterior and, if necessary, the posterior portion of the bowel to double their normal diameter at the point of union, rotation of the anterior peritoneum-covered bowel to secure rapid healing posteriorly, and practically free peritoneal surface anteriorly, stretching or division of the sphincter to secure drainage of the bowel, closure of the colostomy to secure function, and if there be no metastasis and the colostomy is to be permanent, that the rectum be removed at a second operation.

Surgery of the Ileocecal Coil

Dr. Francis Reder, St. Louis: The great danger following a successful resection of the ileocecal coil with immediate restitution of the canal lies in the secondary changes which have taken place in the intestinal walls induced by the disease for which the operation was undertaken. The complete atony of the bowel so often present activates various infective processes generated by the pent-up bacteria. Whenever the virulent contents of the bowel become stagnant at the site of suture, the suture frequently yields and a fatal peritonitis usually results. One of my patients, whose case bore the gravest aspect, developed a fecal fistula on the fifth day after operation and recovered. This happy termination occurred after a patient had died by the ideal method on the ninth day following the operation. It demonstrated to me the fact that a vent became almost a necessary adjunct to this operative procedure. In my last two cases I have successfully employed a technic that carried with it an artificial anus, but in a modified form. The advantage of this technic is a vent that will not require risky operative measures for its successful closure. In the ileocecal resections there have been three deaths following the ideal method, and one in which an artificial anus was made. There have been two recoveries from the ideal method, one following an artificial anus, and two by my method. One patient developed a fecal fistula five days after operation.

Cyst of the Appendix

Dr. Rudolph Matas, New Orleans: I have a specimen of a rare, retroperitoneal, multilocular, retrocecal cyst of the appendix of large size, weighing 1,582 gm., (over 52.7 oz.) which contained a gelatinous, coagulable, myxoid fluid of variable color and consistency. It measured 47.5 cm. in circumference around its longest diameter, 17.5 cm. in breadth, and 10 cm. in thickness (18¾, 7 and 4 inches, respectively), with a perimeter of 56 cm. (22 inches). It is not a retention cyst or hydrops, as the appendix is quite distinct and separate, though attached to the mass. Its origin is doubtful and obscure. It is evidently a connective tissue sac with multiple compartments lined with endothelium, probably an outgrowth of some embryologic relic connected with the mesentery, possibly a development of an original lymphangioma cavernosum of the mesentery. The mass was removed from a young man, aged 25 years, who has recovered uneventfully after the intervention.

1. **Leukocytes in Meningitis.**—All of Hess' cases of epidemic meningitis were associated with a marked leukocytosis. The neutrophils were always the predominating cell before the administration of serum. There was a moderate but absolute lymphocytosis in all cases, most marked during convalescence, except in the one infected with measles. It was most marked in the fatal case. There was always an approximation and in some a crossing of the neutrophil and lympho*cyte curves during convalescence. Eosinophils disappear abso*lutely very early in the infection and do not recur until convalescence has set in. With recrudescence and the reappearance of organisms in the spinal fluid, they again disappear. Although there may be a distinct increase occasionally, at no time in Hess' series of cases was there a marked eosinophilia. Their presence and reappearance in his cases was always associated with signs of good omen. Leukocytosis in pneumonia as in other infections is dependent on two great factors: first, the reaction on the part of the organism, and second, the severity of the infection. This is peculiarly true of children whose course in the typical types is associated with a lower mortality than in adults while in the atypical secondary types, we see the highest mortality of any age except that of senility. Generally speaking, a high count indicates a severe infection in an individual of strong powers, a moderate increase indicates either a slight infection with good resistance, or a severe type with an inadequate reaction. A low count suggests either a slight infection or an overpowering influence. It is impossible to make a reliable prognosis in pneumonia from the leukocyte count alone, however, when studied in relation to the clinical picture, the leukocyte count becomes of great prognostic significance. Primary pneumonias of infancy are usually of the lobar type. Bronchopneumonias are usually either secondary pneumonias or are seen in infants with low vitality. This assertion is based on the physical findings, clinical course and blood findings. Young infants react to infections with a high neutrophil count, the same as seen in older children. The usual blood picture in pneumococcus infections is that of a high neutrophil count with a moderate lymphocytosis before the crisis. A deviation from this picture should lead one to suspect lues, tuberculosis, typhoid or influenzal or other infections or the presence of a rachitis or other complication. Excessively high counts are apparently more prone to the development of empyema and other complications, although it is impossible to say whether or not the hyperleukocytosis is not the result of an already infected pleura, etc., not demonstrable clinically. In several instances the toxic symptoms associated with these high counts have led us to do spinal puncture with negative findings. The neutrophil and lymphocyte curves approximate and occasionally cross each other during convalescence. There is a rapid fall in the neutrophils after the crisis. Pseudocrisis is associated with little or no reduction in the total count. A slow fall in the leukocytes with continued high fever indicates either delayed resolution or complications. This is commonly seen in the secondary pneumonias. Sudden increases in the total and neutrophil counts during convalescence should lead to the suspicion of complications, as should a tendency to remain high. In secondary pneumonias the count varies with the associated complications. Frequently there is a high lymphocyte count.

Eosinophilia.—Eosinophils practically disappear during the height of the disease and usually reappear just before or following the crisis or with the beginning of lysis Their recurrence can usually be considered a good sign Disappearance of eosinophils does not depend on the presence or absence of a leukocytosis When they have disappeared, however the absolute decrease tends to remain until the white count nears the normal. They rarely reach an absolute count much above the normal Their occurrence usually indicates that the infection has passed its acme, and is therefore of practical value for prognosis Their disappearance may be retarded by outside factors as the presence of ascaris lumbricoides in the intestinal tract and repeated pneumococcus infections Their disappearance following their return with beginning convalescence should lead to the suspicion of beginning complications

2 **Disseminated Miliary Tuberculosis of Lungs and Skin**—Northrup submits two helps to the diagnosis in the very young of miliary tuberculosis—one, of the lungs—the Roentgen ray, the other of the skin—the eruption In six cases of infants and young children suspected of disseminated miliary tuberculosis of the lungs, the Roentgen ray has cooperated with other tests to decide the diagnosis Two of the cases have been confirmed by necropsy, one has been corroborated by inoculation into the guinea pig one was confirmed by examination of an excised gland, others by finding bacilli in the throat swabs etc The character of the eruption is papulo vesicular, perhaps more vesicular from the first On the neck, in one case, the vesicles were more like sudamina, a little larger though not as large as the vesicle of chicken pox They were thickly clustered in the neck Later there developed a hemorrhagic zone about the vesicle and a subsequent drying and crusting in the middle of the lesion The completed individual lesion was about 2 mm in diameter The rash was on all skin surfaces, including soles, palms and scalp, with more about the mouth, anus and buttocks

All the patients came into the hospital with the evidence in favor of acute pneumonia, the chart bearing out the general suggestion and appearance of the disease The roentgenogram was really the first means of positive diagnosis, being subsequently confirmed by finding tubercle bacilli The cases presented to the experienced observer the mental picture of pneumonia, but the physical signs of bronchitis

3 **Tardy Syphilis.**—The authors believe without question that in many cases of latent syphilis salvarsan produces a beneficial tonic effect. Whether this gain in weight and general condition in infancy is due to this effect or not, they do not know No doubt the effect is mainly due to the action of the drug on the luetic virus As to parallel results with mercurial inunctions, they have not obtained as rapid a gain, nor has the Wassermann reaction become negative as quickly as in our salvarsan cases They have studied 150 cases and injected over seventy children with salvarsan

4. **Treatment of Rheumatic Endocarditis**—The most important part of the treatment of patients coming in with their first attack, Lucas and Wentworth believe to be prolonged rest Rest offers the best hope of complete cure if carried out over a long enough period The hope for permanently curing endocarditis after the first involvement, lessens almost in geometrical progression with each succeeding attack This rest can be obtained in two different ways, either in a hospital or, if the home permits, it can with careful supervision be carried out there There are very few hospitals to day, the authors claim, that are alive to the importance of long continued rest for these early cases of rheumatic fever, or that are willing to keep such cases in their hospital beds long enough really to ensure a permanent cure of the endocardium If not properly treated during the first attack the infection is likely never to be entirely cured The patient is too often discharged with the infection in a quiescent stage, simply to flare up again under the slightest provocation during a recurrent attack Hospital treatment to be successful in these cases must be continued over months rather than weeks the patients being kept in bed and at rest for at least six weeks after all signs of infection, such as temperature, have passed, and then there should be a very gradual increase of activities, the child being under constant supervision throughout the convalescent period The home treatment of such cases will depend almost entirely on the cooperation of the family and the supervision which the hospital offers for follow up work —a combination which is most difficult But if this can be carried out satisfactorily, it offers several advantages In all of these cases medical treatment plays a minor part as compared with rest As in tuberculosis fresh air plays the most important part in a successful treatment, so in these cardiac conditions rest is the key note for successful treatment We must have fresh air and good food combined with rest, as well as a calm cheerful mind

The medicinal treatment is symptomatic In the primary attacks cardiac stimulants are practically never needed. Salicylates usually in the form of acetyl salicylic acid (aspirin) with sodium bicarbonate, are of considerable value during the acute febrile stage and the use of salicylates from time to time may have a preventive function especially when the patients are exposed to any infection or have been exposed to sudden changes of weather The removal of any infection should be carefully looked into The diet, with special attention to constipation, should be carefully supervised. In cases which present themselves with well developed cardiac lesions, but with as yet no failure of compensation, the same observation obtains and the daily life is so regulated that the least strain possible is put on the heart The diet is regulated thorough mastication is urged, the bowels kept moving regularly The patient is advised to report on the first signs of fatigue pain loss of appetite or dyspnea When a patient comes with broken compensation the *sine qua non* is rest

The plan which Lucas and Wentworth suggest for a study of cardiac cases among children includes a general survey of the actual number of cardiac patients attending the hospitals; an estimate of the number of children with the first attack who should be in some institution, as a cardiac sanatorium for a shorter or a longer time an estimation of how many of these cardiac cases could be cared for at home, if they were properly supervised and followed up, an estimate of the number of practically incurable cases and cardiac cripples should be made and some means of reaching these children educationally vocationally and recreatively should be attempted

5 **Neurotic Vomiting.**—The essential features of the case cited by McClure were The sudden onset of vomiting at the age of 3½ months with retention of breast milk while artificial food was vomited The persistence of the vomiting despite the great variety of liquid foods given, with cure resulting promptly on giving semi solid food The slow, forceless and apparently willful nature of the vomiting without swallowing The neurotic disposition of the child, as evidenced by the development of a head rolling habit The usual causes of persistent vomiting having been satisfactorily excluded, McClure was led to explain the vomiting as a neurotic manifestation

11 Abstracted in The Journal, November 8, p 1743

provide for drainage. I have in some cases left a considerable part of the vesical peritoneum in the vagina, forming a new vaginal vault. A mushroom catheter is put into the bladder for a few days to keep it at rest during the first part of the healing process, and the patient remains in bed from eight to twelve days, the peritoneal drain being removed in from four to six days.

Resection of the Rectum for Cancer with Preservation of the Sphincter

Dr. Charles H. Mayo, Rochester, Minn.: Extirpation of the cecum and ascending colon for cancer has given a high percentage of cures because an anastomosis of the ileum into the colon was an ideal enterostomy for delivering semiliquids. The two-stage Mikulicz method is one of the safest known, although convalescence is protracted. A permanent colostomy, though abhorrent to all patients, undoubtedly gives a higher percentage of cures than do methods which restore function. I advise thorough abdominal exploration; a temporary or permanent colostomy in the majority of cases; increasing the lumen of the anterior and, if necessary, the posterior portion of the bowel to double their normal diameter at the point of union; rotation of the anterior peritoneum-covered bowel to secure rapid healing posteriorly, and practically free peritoneal surface anteriorly; stretching or division of the sphincter to secure drainage of the bowel; closure of the colostomy to secure function, and if there be no metastasis and the colostomy is to be permanent, that the rectum be removed at a second operation.

Surgery of the Ileocecal Coil

Dr. Francis Reder, St. Louis: The great danger following a successful resection of the ileocecal coil with immediate restitution of the canal lies in the secondary changes which have taken place in the intestinal walls induced by the disease for which the operation was undertaken. The complete atony of the bowel so often present activates various infective processes generated by the pent-up bacteria. Whenever the virulent contents of the bowel become stagnant at the site of suture, the suture frequently yields and a fatal peritonitis usually results. One of my patients, whose case bore the gravest aspect, developed a fecal fistula on the fifth day after operation and recovered. This happy termination occurred after a patient had died by the ideal method on the ninth day following the operation. It demonstrated to me the fact that a vent became almost a necessary adjunct to this operative procedure. In my last two cases I have successfully employed a technic that carried with it an artificial anus, but in a modified form. The advantage of this technic is a vent that will not require risky operative measures for its successful closure. In the ileocecal resections there have been three deaths following the ideal method, and one in which an artificial anus was made. There have been two recoveries from the ideal method, one following an artificial anus, and two by my method. One patient developed a fecal fistula five days after operation.

Cyst of the Appendix

Dr. Rudolph Matas, New Orleans: I have a specimen of a rare, retroperitoneal, multilocular, retrocecal cyst of the appendix of large size, weighing 1,582 gm., (over 52.7 oz.) which contained a gelatinous, coagulable, myxoid fluid of variable color and consistency. It measured 47.5 cm. in circumference around its longest diameter; 17.5 cm. in breadth, and 10 cm. in thickness (18¾, 7 and 4 inches, respectively), with a perimeter of 56 cm. (22 inches). It is not a retention cyst or hydrops, as the appendix is quite distinct and separate, though attached to the mass. Its origin is doubtful and obscure. It is evidently a connective-tissue sac with multiple compartments lined with endothelium, probably an outgrowth of some embryologic relic connected with the mesentery, possibly a development of an original lymphangioma cavernosum of the mesentery. The mass was removed from a young man, aged 25 years, who has recovered uneventfully after the intervention.

3 *Tardy Syphilis. H. H. Yerington and F. M. Holsclaw, San Francisco.
4 *Treatment of Rheumatic Endocarditis. W. P. Lucas, San Francisco, and M. H. Wentworth, Boston.
5 *Neurotic Vomiting in Infant. W. B. McClure, Baltimore.

1. **Leukocytes in Meningitis.**—All of Hess' cases of epidemic meningitis were associated with a marked leukocytosis. The neutrophils were always the predominating cell before the administration of serum. There was a moderate but absolute lymphocytosis in all cases, most marked during convalescence, except in the one infected with measles. It was most marked in the fatal case. There was always an approximation and in some a crossing of the neutrophil and lymphocyte curves during convalescence. Eosinophils disappear absolutely very early in the infection and do not recur until convalescence has set in. With recrudescence and the reappearance of organisms in the spinal fluid, they again disappear. Although there may be a distinct increase occasionally, at no time in Hess' series of cases was there a marked eosinophilia. Their presence and reappearance in his cases was always associated with signs of good omen. Leukocytosis in pneumonia as in other infections is dependent on two great factors: first, the reaction on the part of the organism, and second, the severity of the infection. This is peculiarly true of children whose course in the typical types is associated with a lower mortality than in adults while in the atypical, secondary types, we see the highest mortality of any age except that of senility. Generally speaking, a high count indicates a severe infection in an individual of strong powers, a moderate increase indicates either a slight infection with good resistance, or a severe type with an inadequate reaction. A low count suggests either a slight infection or an overpowering influence. It is impossible to make a reliable prognosis in pneumonia from the leukocyte count alone; however, when studied in relation to the clinical picture, the leukocyte count becomes of great prognostic significance. Primary pneumonias of infancy are usually of the lobar type. Bronchopneumonias are usually either secondary pneumonias or are seen in infants with low vitality. This assertion is based on the physical findings, clinical course and blood-findings. Young infants react to infections with a high neutrophil count, the same as seen in older children. The usual blood-picture in pneumococcus infections is that of a high neutrophil count with a moderate lymphocytosis before the crisis. A deviation from this picture should lead one to suspect lues, tuberculosis, typhoid or influenzal or other infections, or the presence of a rachitis or other complication. Excessively high counts are apparently more prone to the development of empyema and other complications, although it is impossible to say whether or not the hyperleukocytosis is not the result of an already infected pleura, etc., not demonstrable clinically. In several instances the toxic symptoms associated with these high counts have led us to do spinal puncture with negative findings. The neutrophil and lymphocyte curves approximate and occasionally cross each other during convalescence. There is a rapid fall in the neutrophils after the crisis. Pseudocrisis is associated with little or no reduction in the total count. A slow fall in the leukocytes with continued high fever indicates either delayed resolution or complications. This is commonly seen in the secondary pneumonias. Sudden increases in the total and neutrophil counts during convalescence should lead to the suspicion of complications, as should a tendency to remain high. In secondary pneumonias the count varies with the associated complications. Frequently there is a high lymphocyte count.

Eosinophilia: Eosinophils practically disappear during the height of the disease and usually reappear just before or following the crisis or with the beginning of lysis. Their recurrence can usually be considered a good sign. Disappearance of eosinophils does not depend on the presence or absence of a leukocytosis. When they have disappeared, however, the absolute decrease tends to remain until the white count nears the normal. They rarely reach an absolute count much above the normal. Their occurrence usually indicates that the infection has passed its acme, and is therefore of practical value for prognosis. Their disappearance may be retarded by outside factors, as the presence of ascaris lumbricoides in the intestinal tract and repeated pneumococcus infections. Their disappearance following their return with beginning convalescence should lead to the suspicion of beginning complications.

2. **Disseminated Miliary Tuberculosis of Lungs and Skin.**—Northrup submits two helps to the diagnosis in the very young of miliary tuberculosis—one, of the lungs—the Roentgen ray; the other of the skin—the eruption. In six cases of infants and young children suspected of disseminated miliary tuberculosis of the lungs, the Roentgen ray has cooperated with other tests to decide the diagnosis. Two of the cases have been confirmed by necropsy, one has been corroborated by inoculation into the guinea pig, one was confirmed by examination of an excised gland, others by finding bacilli in the throat swabs, etc. The character of the eruption is papulovesicular, perhaps more vesicular from the first. On the neck, in one case, the vesicles were more like sudamina, a little larger though not as large as the vesicle of chicken pox. They were thickly clustered in the neck. Later there developed a hemorrhagic zone about the vesicle and a subsequent drying and crusting in the middle of the lesion. The completed individual lesion was about 2 mm. in diameter. The rash was on all skin surfaces, including soles, palms and scalp, with more about the mouth, anus and buttocks.

All the patients came into the hospital with the evidence in favor of acute pneumonia, the chart bearing out the general suggestion and appearance of the disease. The roentgenogram was really the first means of positive diagnosis, being subsequently confirmed by finding tubercle bacilli. The cases presented to the experienced observer the mental picture of pneumonia, but the physical signs of bronchitis.

3. **Tardy Syphilis.**—The authors believe without question that in many cases of latent syphilis salvarsan produces a beneficial tonic effect. Whether this gain in weight and general condition in infancy is due to this effect or not, they do not know. No doubt the effect is mainly due to the action of the drug on the luetic virus. As to parallel results with mercurial inunctions, they have not obtained as rapid a gain nor has the Wassermann reaction become negative as quickly as in our salvarsan cases. They have studied 150 cases and injected over seventy children with salvarsan.

4. **Treatment of Rheumatic Endocarditis.**—The most important part of the treatment of patients coming in with their first attack, Lucas and Wentworth believe to be prolonged rest. Rest offers the best hope of complete cure if carried out over a long enough period. The hope for permanently curing endocarditis after the first involvement, lessens almost in geometrical progression with each succeeding attack. This rest can be obtained in two different ways, either in a hospital, or, if the home permits, it can with careful supervision be carried out there. There are very few hospitals to-day, the authors claim, that are alive to the importance of long continued rest for these early cases of rheumatic fever, or that are willing to keep such cases in their hospital beds long enough really to ensure a permanent cure of the endocardium. If not properly treated during the first attack the infection is likely never to be entirely cured. The patient is too often discharged with the infection in a quiescent stage, simply to flare up again under the slightest provocation during a recurrent attack. Hospital treatment to be successful in these cases must be continued over months rather than weeks, the patients being kept in bed and at rest for at least six weeks after all signs of infection, such as temperature, have passed, and then there should be a very gradual increase of activities, the child being under constant supervision throughout the convalescent period. The home treatment of such cases will depend almost entirely on the cooperation of the family and the supervision which the hospital offers for follow up work—a combination which is most difficult. But if this can be carried out satisfactorily, it offers several advantages. In all of these cases medical treatment plays a minor part as compared with rest. As in tuberculosis fresh air plays the most important part in a successful treatment, so in these cardiac conditions rest is the key note for successful treatment. We must have fresh air and good food combined with rest, as well as a calm, cheerful mind.

The medicinal treatment is symptomatic. In the primary attacks cardiac stimulants are practically never needed. Salicylates, usually in the form of acetyl salicylic acid (aspirin) with sodium bicarbonate, are of considerable value during the acute febrile stage, and the use of salicylates from time to time may have a preventive function, especially when the patients are exposed to any infection or have been exposed to sudden changes of weather. The removal of any infection should be carefully looked into. The diet, with special attention to constipation, should be carefully supervised. In cases which present themselves with well developed cardiac lesions, but with as yet no failure of compensation, the same observation obtains and the daily life is so regulated that the least strain possible is put on the heart. The diet is regulated; thorough mastication is urged, the bowels kept moving regularly. The patient is advised to report on the first signs of fatigue, pain, loss of appetite or dyspnea. When a patient comes with broken compensation the *sine qua non* is rest.

The plan which Lucas and Wentworth suggest for a study of cardiac cases among children includes a general survey of the actual number of cardiac patients attending the hospitals; an estimate of the number of children with the first attack who should be in some institution, as a cardiac sanatorium, for a shorter or a longer time, an estimation of how many of these cardiac cases could be cared for at home, if they were properly supervised and followed up, an estimate of the number of practically incurable cases and cardiac cripples should be made, and some means of reaching these children educationally, vocationally and recreatively should be attempted.

5. **Neurotic Vomiting.**—The essential features of the case cited by McClure were: The sudden onset of vomiting at the age of 3½ months, with retention of breast milk while artificial food was vomited. The persistence of the vomiting despite the great variety of liquid foods given, with cure resulting promptly on giving semi-solid food. The slow, forceless and apparently willful nature of the vomiting without swallowing. The neurotic disposition of the child, as evidenced by the development of a head rolling habit. The usual causes of persistent vomiting having been satisfactorily excluded, McClure was led to explain the vomiting as a neurotic manifestation.

16 Life-History of Dermatobia Hominis. F. Knab, Washington, D. C.

13. **Way to Vaccinate.**—The vaccination process should stop at the vesicle and in order to make sure of this, Dyer says, the physician should see to it that the eruption stops with the vesicle, by purposefully breaking the vesicle and treating the site antiseptically. This practice, Dyer has followed for nearly twenty years, with a happy satisfaction in the knowledge that the proverbial "sore arm" is prevented and that the scar of vaccinia is either avoided, or is reduced to a *minimum*.

The way to vaccinate should be based on the following technic: Clean the area thoroughly with soap and water; follow with alcohol sponging. Be sure the alcohol dries off well, so as to leave the area aseptic but not antiseptic. Vaccinate by any aseptic method; the writer usually employs the point coming with the glycerinized vaccin and the area is scarified. Cover the area of vaccination at once with sterile cotton and hold in place with collodion. A shield may be used over this dressing to prevent its removal. Conduct the vaccination as you would any other surgical case. Have the patient return on the third, fifth and seventh days. If there are no symptoms of itching, or of pain, do not remove the dressing until the fifth or seventh day.

On the day the dressing is removed, if there is no sign of vesiculation, reapply sterile dressing as before. On the seventh day, look again for the vesicles; if none, repeat dressing. Do this every two days until the tenth or twelfth day. If no vesicles show, revaccinate and proceed as before. If the vesicle shows at any dressing, brush the surface with tincture of iodin, then carefully clip the top off of the vesicle with a pair of sterile scissors. Paint the base of the vesicle with a thirty grain to the ounce solution of nitrate of silver, or with pure phenol (followed with alcohol). Put on a sterile dressing, or an antiseptic dressing. Change the dressing every two days. At the end of four or six days, there is a dry crust (not pustulating). Now the patient can take care of the wound, with a dressing of ichthyol (20 grains), phenol (10 grains), ointment (oxid of zinc ointment, 1 ounce), changed night and morning. The evils of vaccination, particularly those incidental conditions following the pustulating arm, Dyer claims, are prevented by such a procedure. There can be no impetigos, and erythema multiforme and its congeners cannot result from pus absorption.

40 Cancer of Lower Lip. J. C Bloodgood, Baltimore.

35. **Effect of Digitalis on Blood-Pressure, etc.**—The effects of various drugs on the blood-pressure, as determined by experiments on animals, in Lawrence's opinion do not furnish reliable criteria for the administration of such drugs to man, since the effect may be quite different in the latter. The pressure-raising effect of digitalis noted by him in animals and in healthy individuals did not occur, as a rule, when the drug was administered to individuals suffering from cardiac decompensation. The cause of the cardiac decompensation did not appear to affect the action of the drug. He states that digitalis preparations may be safely administered to patients suffering from arteriosclerosis, angina pectoris, or nephritic hypertension, if cardiac decompensation is present; under such conditions it rarely causes a rise in blood-pressure.

Of twenty-six cases studied by Lawrence five, or 19 per cent., showed a rise in systolic pressure, the greatest increase noted being 30 mm. There was present in this case an acute infection, involving the heart and kidneys. Of the group of cases showing a rise in systolic pressure, none showed a diuresis. Four cases, or 15 per cent., showed no change in systolic pressure. Of these, none showed a diuresis. Seventeen cases, or 66 per cent., showed a fall in systolic pressure either during or immediately after the administration of digitalis preparations. Of these, 88 per cent. showed a diuresis. Only one case showed a rise in diastolic pressure. There was no diuresis. Four cases, or 15 per cent., showed no change in diastolic pressure. Of these, 75 per cent. showed a diuresis. Twenty cases, or 74 per cent., showed a fall in diastolic pressure, 63 per cent. of these showing a diuresis. Twelve cases, or 45 per cent., showed an increased pulse pressure, a diuresis occurring in 50 per cent. of this group.

39. **Disinfection of Typhoid Stools.**—The method referred to by Linenthal and Jones was devised by Dr. A. M. Kaiser in the Hygienic Institute of Gratz University. It consists of adding enough hot water to cover the stool in the receptacle and then adding about one-fourth of the entire bulk of quick lime (calcium oxid), covering the receptacle and allowing it to stand for two hours. The hydration of the lime generates enough heat to destroy the typhoid organism. While cold water may often suffice, it cannot be depended on owing to the variable quality of the lime. Hot water from 50 to 60 C. will always give the desired results. The lime used should be in lumps, broken up in small pieces and distributed over the stool.

51 Does Cardiac Rhythm Determine Blood-Pressure Variations?—Changes in cardiac rhythm, Wiggers claims, are not the only determinants of blood pressure variations in man They play a part in the variations of systolic and diastolic pressures, the relative importance of which depends on the degree of arhythmia present and on the depth of respiration which, in itself, causes the systolic and diastolic pressures to decrease during inspiration and increase during expiration No degree of rate variation can be regarded as a type The cases range from those in which respiration governs the change of pressures entirely through those in which more or less complicated mixtures of heart rate and respiratory influences intermingle to those in which extreme cardiac variations alone determine the pressure changes The emphatic insistence of Henderson and his collaborators that heart rate changes play a more important part than is commonly recognized in man, Wiggers says, is true in many cases That, in certain cases, it is the only determining influence may also be admitted, but they are in the minority The majority show the intervention of a respiratory influence which controls, at least, the variations of systolic pressure In the light of these results, the doctrine that, in man, an effective venous pressure exists sufficient during all respiratory phases to insure superimposable beats, must be subjected to further investigation

52 Effect of Anilin Dyes on Growth of Bacteria.—Gentian violet and allied anilin dyes according to Krumwiede and Pratt, have a similar influence on bacterial growth, dividing bacteria into two groups corresponding in general to their reaction to the Gram stain Among Gram negative bacteria a strain is occasionally encountered which will not grow on violet agar, differentiating it from other members of the same species or variety The reaction is quantitative, although the quantitative character is more marked with some species than with others The streptococcus pneumococcus group differ from other Gram positive bacteria in their ability to grow in the presence of amounts of dye sufficient to inhibit the other species The dysentery bacillus group shows marked variation in the presence of dyes In the case of fuchsin the variation approaches closely a specific difference between the dysentery and paradysentery groups The variations of the latter groups with other dyes show no correlation with the common differential characteristics A closer study might reveal variations in other characteristics which would parallel the different reactions to dyes Decolorization with sodium sulphite robs the dyes of some of their inhibitive powers

53 Acid Agglutination of Pneumococci.—Eight strains of pneumococci of serological Type 1, eight strains of Type 2, and eleven strains belonging to neither type were tested by Gillespie by the method of acid agglutination Strains belonging to the two typical groups have, as a rule, narrow zones of agglutination. The optimum hydrogen ion concentrations are different in the two cases Other pneumococci have broad zones or, in a few cases, narrow zones not coincident with those occupied by the typical organisms The agglutination of most of the pneumococci of Types 1 and 2 is extremely susceptible to the inhibiting action of salts This is not true of the other pneumococci Old broth cultures may show an optimum hydrogen ion concentration different from that shown by young broth cultures

54 Immunologic Study of Pneumococcus Mucosus.—The organisms described by Schottmuller under the name *streptococcus mucosus* represent a well defined group with characteristics which Hanes says indicate a closer relationship to the pneumococci than to the streptococci The members of this group are specifically agglutinable when treated according to the method of Porges They do not agglutinate when subjected to the usual agglutination methods. Complement fixation experiments with these organisms, compared with similar experiments with two varieties of pneumococci and two streptococci, indicate that they are closely related to the pneumococci No protection of mice against *pneumococcus mucosus* by means of specific immune serums could be demonstrated Hanes suggests that the name *pneumococcus mucosus* should be adopted for this group instead of *streptococcus mucosus*

55 Causation of Chicken Tumors—A causative agent has been separated by Rous and Murphy from three chicken tumors of very different sort, namely a spindle celled sarcoma, an osteochondro sarcoma and a spindle celled sarcoma peculiarly fissured by blood sinuses This was accomplished after the tumors had been transplanted repeatedly and their malignancy enhanced Each of the tumor producing agents is a distinct entity in that it gives rise only to growths of the precise kind from which it has been derived All pass through Berkefeld cylinders impermeable at the same test to small bacteria, and two of the three retain their activity in tumor tissue that has been dried or glycerinated All are strikingly dependent for their action on derangement of the tissue with which they are brought in contact The general findings strongly suggest that the agents are of about the same size, and of the same natural class Rous and Murphy believe that it is perhaps not too much to say that their recognition points to the existence of a new group of entities which cause in chickens neoplasms of diverse character.

56 Goiter in Brook Trout.—Marine found that goiter in fish is a non infectious, non contagious, symptomatic manifestation of a fault of nutrition, the exact biochemical nature of which has not been determined Feeding the highly artificial and incomplete diet of liver is the major etiologic factor in bringing about this fault of nutrition which is at once corrected by feeding whole sea fish Water plays no essential part in the etiology, transmission or distribution of the disease in the fish of this hatchery

57 Tetany in Dogs—Accessory parathyroid tissue unassociated with the thyroid lobes is present in 5 to 6 per cent of dogs For the determination of the presence of accessory parathyroid tissue there are two tests (1) the anatomic, often entailing serial sections of the neck and upper thoracic structures and (2) the biological, consisting of the daily use of some calcium salt for two to three weeks The latter is more easily carried out and more accurate In the absence of all parathyroid tissue calcium salts will not save the animal's life, while in the presence of active parathyroid tissue calcium will save it Many factors other than the amount of parathyroid tissue removed influence the onset of tetany, among which are age, pregnancy, lactation, rachitis, the administration of sulphur and diet

58 Experimental Hydrocephalus—Thomas found that internal hydrocephalus can be produced experimentally by injecting a foreign substance into the ventricles In these experiments, aleuronat, a granular, insoluble material, has caused an acute inflammatory reaction, characterized in the first week by an exudate consisting largely of polynuclear leukocytes Later the picture is one of a chronic process, polynuclear cells are replaced by lymphoid and large mononuclear cells and there is proliferation of the connective tissue in the choroid plexus Proliferation of the ependyma occurs in the first week but becomes more advanced in the second and third weeks, and there is increase in neuroglia more marked in the long con tinued experiments Ordinarily when aleuronat is injected into a serous cavity, the pleural cavity, for example, abundant accumulation of fluid takes place in twenty four to forty eight hours, and at the same time polynuclear leukocytes collect

In the experiments in which the irritant was injected into the ventricle of the brain there was little or no dilatation apparent in the first week, absence of dilatation in all probability is due to the free outflow of the fluid When obstruction occurs during the chronic stage of the inflammatory process dilatation of the ventricle follows Choked disk and other symptoms of increased intracranial pressure accompany experimental hydrocephalus Dilatation occurs slowly and reaches a maximum in about two months In some of the experiments of longer duration obstruction can be demonstrated in gross or microscopically

Obvious obstruction has not been found by gross examination in all instances, but in the experiments in which India ink was injected into the ventricle before death, obstruction to outflow was very readily demonstrated The third and fourth ventricles were in all instances filled with the pigment, but none appeared on the surface of the brain, whereas in normal dogs the entire surface, especially the base, became deeply pigmented Obstruction to the circulation of cerebrospinal fluid causing internal hydrocephalus may occur at the foramen of Monro, in the aqueduct of Sylvius, or, doubtless with greatest frequency, at the foramen of Magendie

63 *Mode of Action of Strophanthin on Cardiac Tissue A J Clark London
64 Time Recorder for Kymograph Tracings O E Closson, Detroit Mich
65 *Mechanism of Stimulation of Medullary Centers by Decreased Oxidation H S Gasser and A S Loevenhart, Madison Wis
66 *Removal of Diffusible Substances from Circulating Blood of Living Animals by Dialysis J J Abel L G Rowntree and B B Turner, Baltimore

63 **Action of Strophanthin on Cardiac Tissue**—Clark found experimentally that the primary effect of strophanthin on the isolated heart is to increase the force of contraction, in the fresh heart the force of the auricular contraction is increased markedly but the force of the ventricular contraction less markedly In the hypodynamic heart the force of contraction of both auricle and ventricle is increased greatly The systolic action of strophanthin is opposed by the presence of acid, by the absence of calcium, and by the hypodynamic condition The action of strophanthin in impairing the rate of conduction is not antagonized, but rather increased by the above conditions This action, moreover, is not antagonized by any other changes in the ionic content of Ringer The action of strophanthin on conduction appears to be largely independent of its action on contraction The acids produced by the heart and which accumulate when perfusion is arrested, can be shown to antagonize the systolic action of strophanthin, and this fact explains why hearts, arrested in systole by strophanthin often relax into diastole and also why hearts in which the conduction is impaired, before any systolic action has been produced, usually die in diastole and not in systole

65 **Stimulation of Medullary Centers**—By decreasing the oxidative processes, Gasser and Loevenhart determined the latent periods of their stimulation of the medullary centers This was accomplished by the administration of carbon monoxid or sodium cyanid The latent periods were found to be so short that the stimulation could not be attributed to the accumulation of acid products They therefore feel forced to the conclusion that oxygen want is of itself a stimulus to the medullary centers

They have shown by a direct method that carbon monoxid stimulates the vasomotor center The early fall of blood-pressure so often produced by carbon monoxid is due to its direct action on the heart The medullary centers respond to the anoxemia produced by carbon monoxid, first by stimulation and then by depression The centers are stimulated and then depressed in the following order respiratory, vasomotor and cardio inhibitory Support is given to the theory that the activity of the medullary centers depends on the condition of their oxidative processes

A theory is tentatively advanced to account for the stimulation of the medullary centers by oxygen want or decreased oxidation according to which the oxidative processes occurring within the cell are of two types those not requiring free oxygen, and of which functional activity is the external expression, and those requiring free oxygen and which result in the storing of potential energy and the removal of the products of activity Stimulation of the latter processes automatically depresses the reactions of activity and depression of the processes characteristic of rest and recovery automatically stimulates those processes of which functional activity is the external expression

66 **Removal of Diffusible Substances by Dialysis**—The principle of the method used by the authors consists in connecting an artery of the animal by a cannula to an apparatus made of celloidin or other dialyzing membrane in the form of tubes, immersed in a saline solution or serum, and providing for the return of the blood to the animal's body by another cannula attached to a vein The tubes and cannulas are filled completely before attachment with a saline solution which approximates in composition to the salt content of the serum of the animal This is displaced into the body by the inflow of blood, when the circulation in the apparatus is established The blood leaving the artery flows through a perfectly closed system and returns to the body within a minute or two without having been exposed to contact with the air or any chance of microbial infection, while the diffusible substances which it contains can pass out more or less rapidly through the walls of the tubes Coagulation of the blood is prevented by injection of hirudin The substitution in the animal's body of saline solution for an equal volume of blood leaves the physiologic condition as nearly as possible unchanged and chemical results obtained by this method may be expected to represent normal conditions very closely, closer, e g, than when large quantities of blood are drawn off for analysis Two animals have made rapid and complete recovery after being subjected to the procedure for two and three hours respectively

72 **Von Ruck's Treatment of Tuberculosis**—McMichael speaks highly of K von Ruck's vaccine He emphasizes that unlike many preparations presented to the profession, there

is absolutely no secrecy regarding the preparation or the details of its manufacture, and any reputable physician is welcomed and afforded every opportunity to study every phase of the work. This remedy, which is a vaccine containing all the soluble products of the tubercle bacillus, in proportions differing from those found in the tubercle bacillus as shown by chemical analysis. After a person, not infected with tuberculosis receives an injection of this preparation his serum develops the property of completely dissolving and destroying the tubercle bacillus in a test tube, a property which his serum did not possess before treatment. When the contents of this test-tube containing the tubercle bacilli killed by the patient's serum, without the addition of any other product are injected into an animal, the animal does not develop tuberculosis. McMichael's experience in treating more than two hundred children and adults with the vaccine has given him many convincing proofs of its efficacy. While this remedy is distinctly not a cure for tuberculosis, he says, it will do all that any of the present known specific products will do toward checking the ravages of the disease, and further, we have in this vaccine, as delicate a diagnostic aid as any we possess, with the added advantage that while using it for diagnostic purposes, we are at the same time employing a remedial agent.

73. **Emptying the Uterus in Eclampsia.**—Since the pregnant state is primarily responsible for eclampsia, Peterson states that the best interests of such patients are promoted by terminating the pregnancy as soon as this can safely be accomplished. The wasting of valuable time in other forms of treatment before operative delivery, is responsible, in great part, for the poor results of treatment in antepartum eclampsia. This is also aided by the selection of the wrong method of delivery of the antepartum eclamptic, whereby the patient is subjected to prolonged anesthesia and trauma and by the resulting sepsis from improper technic in patients whose powers of resistance are greatly lowered by the action of the eclamptic poison. The eclamptic should be delivered as soon as possible after the first convulsion, by the operation giving rise to the least shock and trauma. The eclamptic patient should be delivered first and then elimination started, rather than the reverse. Fortunately, the treatment best adapted to the eclamptic mother, is equally good for her child. Hence, immediate delivery after the first convulsion will result in a low fetal as well as a low maternal mortality.

74. **Chronic Cystic Mastitis.**—Judd believes that chronic cystic mastitis has a definite relationship to cancer of the breast and in many instances may be considered a precancerous condition. In cases suspicious as to malignancy, a radical operation for cancer should be performed. In cases of chronic systic mastitis that cannot either clinically nor pathologically be diagnosed as to malignancy, the conservation amputation with removal of the gland-bearing fascia is the operation of choice.

95. **Experimental Balantidiasis.**—Parasitization of man with *Balantidium coli*, Walker states, is relatively common in the Philippine Islands. The balantidia appear in the stools of parasitized individuals only at irregular intervals, and consequently infections, unless accompanied by clinical symptoms, may frequently be overlooked. A large proportion of the pigs in and about Manila are parasitized with balantidia. Balantidia are passed in the resistant encysted stage more or less constantly in the stools of parasitized pigs. Morphologically *Balantidium coli suis* is identical with *Balantidium coli hominis*. Every person parasitized with Balantidium coli is liable sooner or later to develop balanatidial dysentery. Walker advocates that efficient prophylactic measures against balantidiasis in the Philippines should be directed against these animals, which should be confined and not allowed to run in yards and dwellings.

16 **Nature of Old Age and of Cancer**—Gilford suggests that it may be possible to explain everything that happens in cancer in terms of senility Superficially the cancer process seems very different from the old age process, but if we ignore these superficial distinctions and fix our attention on the more fundamental changes, we see that in reality both are formed on the same plan and are actuated by the same motive Thus, the typical cancer is made up of a collection of cells native to the part but of more embryonic type, and these cells are surrounded by collections of round indifferent cells derived from fibrous tissue and from other low class structures, such as endothelium and leukocytes The fibrous tissue, moreover, is often increased, as it is in the senile organ These changes may be interpreted as follows.

Certain somatic cells become aged while the tissues around them are still in a state of comparative youth They express their senility by returning to a more embryonic form, and as they do so they increase in number, the faculty of multiplication being one of the manifestations of regression But as this qualitative change takes place they become alien to their surroundings, and, as foreigners or rebels, stimulate into action the mechanism of phagocytosis Not only is there an incursion of lymphocytes into the parts, but the connective tissue and endothelial cells in their vicinity revert to their embryonic state and begin the work of phagocytosis But as a fact they have to deal neither with the effete products of molecular degeneration nor with an inert foreign body, for though virtually strangers, cancer cells are by no means inactive

Hence the attack is abortive, except in so far as the phagocytes, by forming new fibrous tissue, tend mechanically to limit the proliferation of the cancer cells For in the meantime the fixed connective tissue cells are themselves rapidly proliferating, with the result that when they cease their activity and return to their resting stage groups of cancer cells are cut off by intersecting bundles of fibrous tissue, while the whole mass is surrounded by an incomplete capsule of the same structure This tends to limit the encroachment of the growing cancer, and were it not for the lymph spaces or capillaries, which are the gaps through which the growing cells escape, no doubt the limitation and strangulation of cancers would occur far more often than they do

The more nearly the cells of a cancer approach the embryonic state the more rapid will be the growth, the less opportunity for fibrosis the more malignant the cancer In senile decay the cells of highest type, or the more specialized cells, do not proliferate but undergo molecular decay, whereas those of lowest type express their degeneration not in decay, but in proliferation So, also, cancer elements are never derived from these same higher kinds of cells, but invariably from the lower kinds Moreover, the lower the type of cells to become the basis of the cancer process the greater is its malignancy It is neither the appearance of phagocytes, nor the increase of fibrous tissue, nor the proliferation of the cancer cells, which constitutes the cancer process The root of the matter lies in the fact that the cancer cells have receded from a state of comparatively high development to a state of comparatively low development Regression is the motive which prompts and animates the whole series of changes

20 **Lithopedion**—The case presented by Fraser has three interesting points (1) The marked reduction in size and weight that took place during calcification (2) The length of time it was carried by the mother, namely, forty two years—possibly the world's record (3) The comparatively slight disturbance it caused for almost forty years, and then only indirectly, as the costiveness was caused by the fibromyoma narrowing the lumen of the intestine to one third of an inch Early in the year 1870 a small, active woman, then aged 25 years who had had three children, became pregnant for the fourth time Matters progressed as usual for six months then seemed to stand still, later the milk left the breasts, fetal movements lessened and finally ceased Her girth decreased, and in a few months only a firm mass was felt at the brim of the pelvis

Anxious and puzzled, she consulted a doctor, who doubted that she had been pregnant, and advised leaving the mass alone as long as no serious inconvenience was felt She followed his advice, and as time passed she had four more children, at each pregnancy the mass rose with the growth of the fetus, and returned to its old position after the birth of the child

In January, 1912, she consulted Fraser for long continued costiveness, which she said was increasing She did not then tell him of the events of 1870 He tried cathartics with only temporary relief, then suspecting obstruction an examination showed more than one mass in the pelvis He operated and found a lithopedion at the brim of the pelvis, the head was easily movable, but the lower part of the body was almost surrounded by firm cartilaginous bands attached to the uterus, omentum and intestines The calcified placenta was found opposite the third sacral vertebra, and so bound down by adhesions that it was difficult to remove it To make matters worse, a fibromyoma had formed in a loop of intestine where it touched the placenta, thus Fraser had to resect over 3 inches of the intestine, the adhesions made this much more difficult The head was covered by a thin membrane containing some blood vessels, the anteroposterior circumference was 8¾ inches and the occipital menti circumference 9⅛ inches, the frontal, parietal and occipital bones were well marked, and there was only a slight depression of the fontanelles, the eyes, nose, chin and mouth were easily seen, the head was flexed and turned toward the left shoulder, and had a rough, stony feel The legs and arms were flexed, with their outlines more visible on the right side, the ribs on the right side were easily seen, but the spinal vertebrae were indistinct The placenta, somewhat biconvex, and with the center more friable than the outer surface, measured 9¼ inches in circumference, and was ⅞ of an inch thick in the center

26 Malaria and Color W H Kenrick

25 **Relief of Renal Pain**—The condition in the case cited seemed to Munro to justify an exploratory operation, and accordingly the kidney was exposed by the usual lumbar incision and brought out in the loin It was large No stone or tumor could be felt in the pelvis which was not dilated To outward appearances the whole kidney was absolutely healthy The pelvis was incised, and a probe passed down the left ureter to the bladder—it passed easily A sterile solution of methylene blue was injected into the opening made in the pelvis of the kidney and was immediately afterward recovered from the bladder The kidney was explored from side to side with a fine trocar, no stone was found, and no pus The opening in the pelvis was accordingly closed with fine catgut sutures which did not include the whole thickness of the wall, and the kidney replaced A drain was put in for twenty four hours

The wound healed by first intention, and for three weeks the patient was pleased with himself The paroxysms of pain then began again though slighter in degree and the urine was found to contain pus and red blood corpuscles Tubercle bacilli and bacillus coli communis were looked for, but not found A month after the operation Munro performed cystoscopy The left ureteric orifice was found to be a little reddened—the bladder was otherwise healthy in appearance The urethral catheter was passed for 9 inches up the left ureter, and 1 ounce of warm boric lotion injected At once a worm like caseous cast of the ureter began to squeeze its way out alongside the urethral catheter The catheter was withdrawn and was followed by a gush of pus The bladder was then relieved of the turbid fluid which it contained and which was obscuring the view, on refilling the bladder with clear lotion a number of caseous worms were seen lying on its base. The urethral catheter was again introduced and another ounce of warm boric lotion injected, which returned blood-stained. This procedure again relieved the patient, and he was free from severe attacks of pain for a month. The only kind of pain from which he suffered from then was apparently intestinal, at any rate it was quickly relieved by carminative mixture, and there was no tenderness on pressure over the kidney area.

Ten days after the second cystoscopy his urine still contained pus cells, and Munro determined to wash out the pelvis of the kidney again. At this, the third cystoscopy, three ounces of 0.5 per cent. silver nitrate solution were injected. Some turbid, but not caseous, pus escaped alongside the catheter on this occasion. The urine remained clear from then on till his discharge from the hospital a fortnight later.

27 *Some Points in Diagnosis and Treatment of Granular Kidney. S. West.
28 Concussion Cataract: Its Medicolegal Aspect; with Report of Unusual Case. P. Dunn.
29 *Relation of Thyroid to Antitoxin. R. Farrant.

27. **Granular Kidney.**—Speaking of the use of a renal extract in granular kidney, West says that he has tried various methods, and for a time used a glycerin extract. He now uses an extract of kidney freshly prepared as required, using by preference the kidney of the pig, as being a mixed feeder, rather than the kidney of a vegetable feeder like the sheep. The great difficulty in obtaining evidence in favor of the usefulness of kidney extract in chronic renal disease, West points out, lies in the fact that its use must be continued for weeks or months before results can be expected; generally patience is exhausted before the time required, and the treatment given up because signs of improvement are not immediate. In granular kidney the cases come under observation so late in the disease, when the mischief is so far advanced, that much benefit can hardly be looked for. Yet he has seen some of the symptoms, especially headaches, relieved by this means when they had resisted other treatment and he cites a case in point.

The patient was a man, aged about 35, who had a typical chronic parenchymatous nephritis. He was passing a very large amount of albumin in the urine, was extremely anasarcous, with much ascites and a considerable pleuritic effusion on the right side. Both the abdomen and pleura had to be tapped more than once, but the fluid reaccumulated quickly. The man was regarded as a hopeless case. All the ordinary treatment was tried without success, the patient steadily went downhill, and the prospect seemed desperate. Renal extract was now given night and morning. In a few days he felt much better. The improvement soon became obvious, the effusions and the dropsy disappeared, slowly at first and then rapidly, and in about three weeks had vanished. The albumin in the urine also rapidly decreased, and on leaving the hospital about six weeks later amounted to a mere trace. The man was carefully watched for some months. He went back to work and remained well. West feels that his experience of some years justifies him in continuing and advocating the use of renal extract, but to be effectual in granular kidney it must be patiently and continuously perservered with for a long time.

Another case was that of a man 40 years of age, with the history that he was attacked with uremic fits about six months before West saw him, and on examination of the eye advanced albuminuric degeneration with much hemorrhage was discovered. A grave prognosis was given. West thought the case almost hopeless, but put him on renal extract, which was steadily persevered with for many months. He gradually recovered and is now well. The fact of his complete recovery from the eye as well as the renal symptoms makes West feel some hesitation about the correctness of the diagnosis, but the condition seemed plain enough at the time, and no one who saw him when first ill, either physician or ophthalmologist, had any doubt.

29. **Thyroid and Antitoxin.**—Farrant obtained the thyroids from fifteen horses that had received increasing doses of diphtheria toxin for a period of a year to eighteen months. It was found that they presented a varying degree of hyperplasia, but that when they were arranged in order, from the highest degree of hyperplasia to the lowest, they were in the reverse order of the antitoxic value of the serum. The apparently normal thyroid corresponded to the serum with the highest antitoxic value. Fifty-eight guinea-pigs were arranged in twenty-nine pairs, each of a pair being similar in appearance and weight. They were injected with different doses of diphtheria toxins. Half were otherwise untreated, the other half were given doses of thyroid powder. Eighteen—that is, nine pairs—were injected with doses of diphtheria toxin from 1 c.c. to 0.1 c.c. daily (a single minimal lethal dose was 1 c.c.); half of these pigs were otherwise untreated, the other half at the time and twenty-four hours previously were given thyroid powder by the mouth in doses from 0.06 to 0.01 gm. daily until they died. Four of the guinea-pigs given thyroid outlived the controls, 2 died before, and 3 died on the same day.

Six guinea-pigs were divided into three pairs, and every one received a single dose of toxin, from 1.4 to 1 c.c. Three were otherwise untreated; the other three were given a corresponding dose of emulsion made by pounding up six fresh guinea-pigs' thyroids with saline. Two of the guinea-pigs given thyroid lived the same number of days as the controls; the other one died two days before. Two rabbits were fed with 0.5 to 0.3 gm. of thyroid powder by the mouth every day for seven days; one had lost 42 per cent. of its weight, the other 15 per cent. They were bled out and the blood defibrinated and centrifugalized. The serum was injected in doses from 1 c.c. to 0.25 c.c. into 14 out of 28 guinea-pigs arranged in pairs. They were all given a single dose of 1½ times the minimal lethal dose of diphtheria toxin. Three of the guinea-pigs given the serum survived, 2 lived longer than the controls, 6 died on the same day, and the other 3 died before the controls. From this it is deduced that the serum of a thyroid-fed animal has practically no antitoxic value.

37. **Treatment of Pott's Disease.**—Broca and Trèves call attention to the cure of severe Pott's disease in five typical cases, described in detail, in which the children never left Paris, but spent three years stretched on a portable bed without other care than that given by their parents. They are now well and merely wear a small supporting corset as a precautionary measure. Lannelongue's technic was followed; it is not applicable when the family are not able to care properly for the child. Consequently the children of wage-earners require a plaster cast, as less attention is necessary with this.

42. **Inherited Syphilis with Tardy Manifestations.**—Alsberg reports a case of tertiary manifestations of syphilis in a child of 4 brought to the clinic on account of exophthalmos of one eye and caries of the skull. The local processes were benefited by iodid and mercury, but the general health suffered so much from the latter that they had to be stopped. There was no certain evidence of syphilis in the parents, and they refused to permit the Wassermann test in the family.

43. **Action of Tuberculin.**—This communication from Baginsky's service asserts as the result of years of clinical and experimental research on the subject, that tuberculin has no immunizing effect. This fact must be constantly borne in mind. The probable mechanism of the change for the better that follows its use, must be that in the small doses in which it should be given it has a stimulating action on the white blood-corpuscles.

44. **Dysentery in Young Children.**—In an orphan asylum at Düsseldorf an endemic of Flexner dysentery developed among the children, sparing 11 breast-fed infants; all but 7 of 29 bottle-fed infants gave a positive seroreaction and over a third of all the children had the dysentery. Examination of the stools proved the only reliable means to differentiate the disease. Young children seem to be specially susceptible to this type of dysentery; none died, as the children in this institution were all in remarkably good health at the outbreak of the endemic.

45. **Rachitic Deformities.**—The wonders that can be accomplished by osteoclasis plus osteotomy are shown in over twenty-two illustrations.

48. **Tuberculosis in Infants.**—Cassel states that six cases of active tuberculosis developed among the 1,282 children at the children's asylum in his charge during the last nearly eight years. The temperature chart shows the first onset and the course of the disease in three cases, the temperature findings being recorded for practically the entire life of these three infants. The first sign of anything wrong was a slight rise in temperature noticed in the sixth, eighth and eleventh week in one case; the other children already had fever when admitted. The fever was of a remittent character with abrupt rise at evening and drop in the morning. Notwithstanding the fever the children gained almost normally in weight for a time. A number of the other children have been thriving and seem to be in good health although at one time they reacted positively to the skin tuberculin test. Tuberculosis in infants thus is not necessarily always fatal.

49. **Acute Encephalitis in Children.**—Comby says that acute, non-suppurative encephalitis is quite common in children, especially in infants, and in them more common after weaning. It is rare after 7, and exceptional after 10. As a rule it follows some infectious disease or process, and the first sign is usually a convulsion. The treatment is that for acute meningitis and later for sclerosis of the brain which is the frequent outcome.

50. **Little's Disease.**—Concetti gives forty illustrations as he describes the various forms in which Little's disease may manifest itself. His work is based on eighty-four cases with necropsy in seven, and all the data confirm his assumption that the trouble is essentially the arrest or partial loss of the normal relations between the brain and the spinal cord, that is, the primary or the cortex-medullary neurons are unable to develop properly or to do their function normally. The result of this may be a number of widely differing syndromes, as he enumerates in detail. As the shorter neurons complete their development first, they may functionate normally while the longer neurons, those governing the legs for instance, show still defective functioning.

52. **Course of Tuberculosis in Children.**—Czerny declares that his many years of observation of the course of tuberculosis followed throughout the child's life has demonstrated beyond question that the condition of the nervous system is a decisive factor in the outcome of the disease; in children with an excitable nervous system the disease runs a more rapid and malignant course. Children with a sound, not easily excited nervous system do much better. The food has far less to do with the outcome. The nervously excitable children have a very unstable circulation, that is, distribution of the blood-supply. It is much livelier than in the more phlegmatic, and this is what keeps constantly whipping up the tuberculosis.

The excitable nervous system is born with the child, but it can be rendered more or less irritable by the way the child is being brought up, and this is a very important argument in favor of the tranquil environment of a sanatorium for children. Conditions in the home may be made to approximate this, but they seldom do. The open air, moving air, he says, is the most important factor in the cure; sunlight is a minor factor, and he has never witnessed improvement under tuberculin that could not be paralleled or surpassed in other cases without the tuberculin. He has noticed that the course of tuberculosis in children is aggravated and new foci developed when the children took a course of drinking mineral waters. Meat and vegetables twice a day, very little milk, and cod liver oil to supply fat are the main reliance in diet, striving to keep down the intake of fluids and consequently not trying to make the children increase in weight Another point to which he pays special attention is to prevent the development of a fistula, the most rebellious foci are generally those with an existing fistula Puncture in time to prevent a fistula is extremely important

72 **Training the Muscles as Prophylaxis of Tuberculosis**—Roeder has long advocated and carried out long hiking trips for boys and girls as an important aid in the physical development of the young His experience in this line has convinced him that the muscular effort involved is the main beneficial factor, the other factors are subsidiary The corollary follows that it is possible to obtain good results with systematic muscular exercises at home or in school By training the muscles of respiration it is possible to develop conditions in the lungs which render them refractory to tuberculosis He has organized a society which plans and provides for these hiking trips for boys and girls between 11 and 14, and he has watched the influence on their development of these systematic *Jugendwanderungen* The results have far surpassed all expectations; the trips each time started a new era of growth and development in the children in their several days of life in the open air with exercise and good food He extols them as a method of biologic prophylaxis against tuberculosis during the second period of growth, when the young are most inclined to develop tuberculosis

73 **Feeble-Minded Children**—Schlesinger devotes 130 pages to his study of the physical and mental development of backward children during the school age and the provisions which they require then and afterward He gives 100 case histories and sixty five illustrations of the children, and urges the necessity for special colonies technical schools and other measures to reduce to the utmost the handicaps under which these young people suffer

74 **Sterile Raw Milk**—Schlossmann gives an illustrated description of an apparatus which sprays the milk under pressure heating it momentarily and then cooling it rapidly Milk thus treated, he states, is sterile while it retains all the properties of raw milk

81 **Dispensary Tuberculin Treatment of Children.**—Wolff reports fourteen cases of children with tuberculous lymph nodes or other focus given a systematic course of tuberculin treatment at the policlinic The results were good, but he thinks that about as good results could have been realized without the tuberculin It certainly did no harm under his cautious dosage

82 **Mistaken Diagnosis of Poliomyelitis**—Zappert reports a case of mild and completely cured poliomyelitis in a child of 3, there had been merely a few days of what was supposed at the time to be a febrile influenza After subsidence of the fever, the family noticed that the child refused to get up and at first screamed if its legs were handled The left knee jerk was attenuated and this leg dragged a little after the child got up, but normal conditions in every respect were soon restored The retrospective diagnosis was unmistakable In three other cases the disease had been mistaken for diphtheria, and antitoxin injected. The primary paresis of the muscles of respiration may be taken for diphtheric croup, and the paralysis of poliomyelitis which develops with a sore throat may be taken for postdiphtheric neuritis He warns further that poliomyelitis may be accompanied by an eruption with desquamation suggesting scarlet fever, but differing in several points from the latter as careful investigation will reveal

In another case acute otitis and beginning pneumonia had been diagnosed, but the extent of the râles caused some hesitance The extreme dyspnea rendered the prognosis grave, and the physician was surprised to find two days later that the fever had dropped and the dyspnea improved, while the reflexes were found impaired and some paresis of the legs was noticed The assumption then of poliomyelitis was justified by the subsidence of all symptoms except that slight paresis of one leg persisted for a time The ears proved to have nothing the matter with them The patient was a boy of over 3 Wolff thinks that this case throws light on many cases of sudden fatal bronchitis in infants; instead of bronchitis, the trouble in reality was poliomyelitis The reflexes should be tested as a routine measure in case of suspected pneumonia or bronchitis in children In another case acute articular rheumatism was mistaken for poliomyelitis, this blunder prevented the routine treatment for the polyarthritis

89 Case of Hour Glass Stomach, Gastric Ulcer and Perigastritis I W Hopmann

83 **Test of Pancreas Functioning.**—Matko states that the pancreas may secrete too much or too little pancreatic juice, and that the test described will give exact information as to which if either of these conditions prevails, and it permits quantitative estimation of conditions In the morning the patient takes fasting a chop weighing 130 or 150 gm without bone or fat and a capsule containing 0 3 gm carmin Two hours later he is given 15 gm Carlsbad salts dissolved in 200 c c water and 200 c c additional water A similar dose is given the evening before, half an hour after an exclusively fluid supper The proportion of pancreatic ferment in the stool varies at different hours, so he has all the portions of stool voided during the day set aside in a cool place All the carmin tinted portions are finally poured together, measured and filtered The first few cubic centimeters are thrown away as too turbid and the rest of the clear filtrate is tested for the presence of trypsin by its power to digest casein in a set of graduated test tubes (Orlowski Gross) The findings are always calculated by the total amount of stool, not by the proportion in the test tubes alone Investigation of the antitrypsin property of the blood serum revealed a remarkable parallel behavior

85 **Automatic Drainage of Stomach and Duodenum**—Bondi writes from von Noorden's clinic to describe a method of examining conditions in regard to the functioning of the stomach and duodenum which seems to be free from several of the drawbacks of other methods The patient swallows a duodenal tube with perforated olive tip The swallowing proceeds more easily if the patient sucks with his lips as the tube passes downward Then the patient reclines on his right side, the end of the tube hanging free over the edge of the bed With normal persons, fluid soon begins to drip from the tube The flow of fluid is not hastened by aspiration but it is left to flow automatically, and by this means exceptionally instructive findings are obtained

The method has been applied 200 times in all, to 153 persons, and it has thrown light on normal and morbid conditions in the stomach, duodenum and connected glands The findings are peculiarly instructive in cases of atony of the stomach and hypersecretion By examining the different portions of the fluid at different intervals, the condition in regard to the different digestive ferments could be traced with extreme precision The variations in the bile tint of the alkaline secretions at different times revealed an occasional nervous inhibition of the flow of bile, a phenomenon probably important in the pathogenesis of gall stone colic The method also discloses whether the bile duct is completely or only partially obstructed Blood was found in the duodenal content not only with duodenal ulcer, but in certain other conditions The bile could be tested for urobilin; it showed abnormally high proportions in certain affections of the blood producing organs Another instructive finding was the discovery of pus cells in the duodenal content as a sign of gall-bladder disease Numerous bile casts were found in the sediment in a case of severe liver disease A number of typical cases are related recording the findings with this continuous automatic drainage of the stomach and duodenum in various morbid conditions

98 Acute Necrosis of the Pancreas G Ricker

97 **Spontaneous Separation of the Epiphysis**—Schwarz gives eight roentgenograms and several case histories to sustain his view that the epiphysis at the upper end of the femur does not become separated suddenly under the influence of a trauma Conditions are more complex here than at similar points elsewhere Even a very slight trauma may suffice to loosen the epiphysis but this is not evident on roentgenoscopy as the tough capsule prevents dislocation Gradually the separation becomes complete as the child uses the limb The trauma generally is so slight that it is unnoticed at the time or is soon forgotten Only later and gradually is attention attracted to a slight limp Then coxa vara develops, as the first stage, the final stage being the complete separation of the head from the neck The neck may gradually waste away from lack of adequate nourishment Beside this typical affection, there may be spontaneous fracture of the neck of the femur in that a wedge shaped piece is separated from the lower half of the neck but still clings firmly to the epiphysis The explanation of this is a primary congenital coxa vara

105 Chemical Composition and Physiologic Action A Langgaard
106 *Vaccine Therapy of Cancer (Der gegenwartige Stand der Behandlung der bosartigen Geschwulste) F Blumenthal

100 **Recent Conquests in Brain Surgery.**—The two patients whose cases are described and illustrated were presented at a recent meeting of the Berlin Medical Society One, a woman of 24, had had a round celled sarcoma, measuring 5 5x6x8 cm, removed from the region of the optic thalamus The other, a boy of 10, had had a small fibrosarcoma removed from the region of the corpora quadrigemina with complete success, all the symptoms of pressure on the brain subsiding The focal symptoms are still improving, day by day The one symptom that persists most tenaciously is the abolition of the pupil reflexes There is also tachycardia The technic followed in this case permits ample access to the pineal gland as well

103 **Cholera.**—Eckert concludes from his experience in the Balkan campaign that a clean and perfectly drained city need have no fear of cholera Notwithstanding the constant importation of fresh cases of cholera into Sofia which is drained by mountain streams, no epidemic resulted Only twenty four cases out of 160 in which the details were known originated in the city and twelve of these were in soldiers or those who tended them One month there were 600 cases of cholera in the hospital but there was no instance of hospital infection known, although other patients frequently came into contact with the cholera cases Flies did not seem to carry the infection, it seems evident that a large number of germs are necessary to transmit cholera.

106 **Vaccine Therapy of Cancer.**—Blumenthal concludes from his review of what has been attempted and accomplished in this line, that the results justify further work with vaccine therapy of cancer He advises when the cancer is inaccessible or the seat of severe mixed infection to make the extract for the vaccine from an analogous accessible tumor on another person Success depends on the practical identity of both growths

107 *Appendicitis in Switzerland C Roux and F de Quervain

December 13, No 50, pp 1657 1688

108 *Successful Operative Treatment of Embolism (Erfolgreich operierter Fall von Embolie der Arteria femoralis und der *Arteria profunda femoris*) *H Matti*

107 **Appendicitis in Switzerland.**—The experiences here related were presented at the inaugural meeting of the recently organized Swiss Surgical Association, which opened with a membership of 112 In his presidential address, T. Kocher of Berne pleaded for the cooperation of the surgeon with the internist in the borderland affections, without waiting until operative treatment becomes imperative The internist should call the surgeon in to consult with him early in the case, so that the progress, up or down, could be interpreted by specialist skill in every direction

Roux' discussion of appendicitis was based on his own experience and de Quervain's on a collective investigation throughout Switzerland All the cases of appendicitis given operative treatment in Swiss hospitals during the last five years are classified as the operation was done the first, second, third or fourth day or later A colored chart illustrates the data and also the findings in the appendix the first or second day, and the date when the patients left the hospital, compared with the day at which the operation was done In some previous collective statistics (1895) only 6 5 per cent of the 7 213 patients were given operative treatment, while the later statistics show 83 3 per cent operated on among 6 116 patients and in Roux' service 91 5 per cent of 404 cases All the speakers reiterated that the fate of the patient lies in the hands of the physician who sees him the first day

108 **Operative Treatment of Embolism**—The right femoral artery suddenly became obstructed with an embolus, as was rendered evident by the sudden intense pain in the right foot and leg and shutting off of the circulation below The patient was a man of 70 with failing compensation of a heart defect A pulse could be felt in the artery down to 3 cm above Poupart's ligament, and Matti decided to cut down on the artery rather than to amputate He removed five embolic plugs, but as the blood even then did not flow from the peripheral artery, he stroked it upward and thus worked out a fresh clot, 15 cm long Over thirteen hours had elapsed before the operation, and yet the circulation was restored at once and completely except in two toes, which became mummified later The advanced arteriosclerosis was probably a factor in this There were signs later of thrombosis in the artery, and necropsy showed that the thrombus was adherent to the walls beyond as well as at the site of the suture It caused no appreciable disturbance except reduction of sensibility in the lower half of the leg The patient died two months after of his heart disease plus pneumonia In conclusion Matti compares his case with ten other recorded operations of the kind on the femoral artery, remarking that his case is the third successful one, and is remarkable for the age of the patient, the others were men of 31 and 43 He regards Murphy's case as a dubious success (The Journal, 1909 lii, 1661)

109. **Outlook for the Campaign against Tuberculosis.**—Loeffler thinks that a new era of progress will dawn in the prophylaxis and treatment of tuberculosis when Wilkinson's method is more widely adopted. He has been investigating at London Wilkinson's tuberculin dispensary method, and witnessed for himself the outcome after five years—almost 100 per cent. of cures in the first stage of tuberculosis and 60 or 70 per cent. of cures in the second stage. The treatment is begun with minute doses of bovine tuberculin, gradually increasing the doses and the strength of the tuberculin and then changing to Koch's "old" tuberculin, continuing with this in increasing doses to a maximum of 0.01 or 0.02 c.c. Wilkinson has succeeded in organizing a "Tuberculin Dispensary League" so that means to equip and maintain numerous dispensaries are available. His principle is "early diagnosis and treatment, before lung tissue has been destroyed and before the wage-earning capacity has been reduced." The tuberculin treatment does not interfere with the patient's occupation if the dispensary is convenient of access, and Loeffler urges the organization in Germany of a similar chain of dispensaries as the next great advance in the campaign against tuberculosis.

112. **Local Factors in Epidemics.**—Kossel expatiates on the way in which laboratory research has solved problems which epidemiology alone could never have solved. It has shown that the old conception of seasons and localities as breeders of certain diseases is readily explained by the life-habits of certain insects and rodents and by the movement of the population, traffic, transportation, etc. He denounces Emmerich's theory that certain soils have a favoring and others a destructive action on disease germs, especially the cholera vibrio, saying that the ground is covered up so much now with pavements and buildings that the "soil" would have little chance to act on the germs in many places.

113. **Milk as Source of Typhoid.**—Fischer reviews the lessons learned from a number of epidemics of typhoid in northern Germany of recent years. The importance of milk as a carrier of the disease was amply demonstrated in these experiences and the promptly effectual means of stamping out the epidemics by seeking out and removing from the handlers of the milk all persons who were found to be chronic carriers.

114. **Typhoid Bacilli Carriers.**—Lentz states that in the Oberstein district typhoid for years had been endemic when, in 1903, the authorities took up the matter and discovered a dangerous chronic carrier. The next year six more were found, and two in 1907 and one in 1908. These carriers were mostly women and mothers of large families They were instructed as to the dangers from them to others and were repeatedly rewarned of the necessity for extreme cleanliness It was impressed on them that after defecation and again before touching any article of food, even buttering a slice of bread, they must wash their hands systematically and thoroughly with soap and water and, before laundering, their under linen and bed linen must be put to soak for twenty-four hours in strong soapy water. Attempts to enforce more vigorous measures met with some resistance, but these simple precautions and reiterated warnings have proved effectual, only one case of typhoid being known in the district during 1912 and two this year

117 and 118 **Biology of Tubercle Bacilli.**—Lockemann and Möllers state that the weight and antigen content of tubercle bacilli cultures increase up to the sixth week and then both show a decline Lockemann says that weighing the cultures now and then gives oversight as to the course of the growth.

131. **Radiotherapy in Gynecology.**—Stoeckel says that although it is too early yet to form a decisive opinion on the value of Roentgen-ray and radium treatment of pelvic diseases in women, yet the results to date have been better than ever realized before under other measures. The radio-active substances have been applied hitherto by the technic borrowed from the Roentgen experience, but time may show that they require a special technic for them. Systematic biologic research is urgently needed to determine the best filtering technic, the dosage and the optimal distance from the focus

Roentgenotherapy is equivalent to operative castration For cancer this is not enough, and since it has been found that the gamma rays of the radio-active substances surpass the Roentgen rays in penetrating power, these are being used for cancer more and more, and even the most skeptical must admit that nothing has ever yet been known with such an enormous primary destructive action on cancer cells. The extent of this destructive action is the problem now; the microscopic findings in the adjoining tissues have been surprisingly favorable in some cases but ominous in others. We do not know what is occurring in the regional lymph-nodes and possibly already infected lymphatics. For gynecologic purposes at least 0.1 gm. of the radium salt or mesothorium are necessary, and this costs over $7,500. The sudden demand for mesothorium far outran the supply, and the manufacturers' trust combined and cornered the market, so that a previously unheard of situation has developed, rendering further therapeutic research in this line a matter of financial resources. Never before has Science had to bargain and beseech in the market place for a chance to try out her new therapeutic discoveries.

132. **Carcinosis of the Lungs.**—Schmidt reports a case in which he made the correct diagnosis during life of miliary carcinosis of the lungs The patient was a woman of 36 who began to cough and have difficulty in breathing, with other

symptoms suggesting miliary tuberculosis but the normal heart and lung findings, afebrile course and absence of the diazo reaction excluded this. The intense dyspnea and tachypnea and the discovery of enlarged lymph-nodes in the left supraclavicular region confirmed the presumptive diagnosis of miliary carcinosis and necropsy two months after the first symptoms corroborated this. In a second case the carcinosis was assumed during life and post mortem to be miliary tuberculosis, until the microscope revealed the carcinosis. In both cases a minute cancer was found in the stomach, and Schmidt thinks this is generally the rule: minute primary cancer plus great tendency to metastasis; large primary cancer, little metastasis. He suggests that possibly in large cancers toxic substances are formed in such profusion that antibodies are generated in response, which practically immunize the rest of the body. Miliary carcinosis of the lungs seems to affect mostly young persons; the nine other cases he cites from the literature were all in persons from 23 to 36 with the exception of one aged 74.

134. **Amenorrhea During Lactation.**—Thiemich has had conditions investigated in 1,200 cases and has found it a universal rule that as long as the women suckled their infants and gave them no other food, there was no menstruation and no new conception. Large families, with ten or twelve children, he has never encountered except among wage-earners and only when the infants were brought up on artificial food after the first week or two. The mothers, not nursing the child, soon menstruated again and a new pregnancy speedily followed. Another fact brought out by his research is that in these large families only 50 per cent. of the children survive the first year. The mothers thus unduly prolific were found invariably much debilitated and their babies were puny. Everything, therefore, points to the vital importance of breast-feeding, if for nothing else to protect the mother against a new pregnancy until she is physiologically ready for it.

139. **The Blood-Pressure and the Composition of the Blood.**—The data presented by Münzer show that many cases of anemia are distinguished by lymphocytosis and low blood-pressure for which a constitutional inferiority of the glands with an internal secretion is unquestionably responsible—the thymic-lymphatic status. Persons with lymphocytosis and low blood-pressure stand general anesthesia badly, while persons with high blood-pressure usually stand it well. This is easily understood by the connection between the blood-pressure and the ductless glands, especially the chromaffine system. The chromaffine substance is used up during general anesthesia, and consequently persons with a constitutionally inferior chromaffine system are liable to suffer most from it. The discovery of lymphocytosis and a low blood-pressure thus warns of the need of caution before attempting an operation under general anesthesia. Persons with high blood-pressure and normal or subnormal numbers of lymphocytes in the blood have a sound and vigorous chromaffine system and are thus able to take the anesthetic without harm, other things being equal. He adds that the various diatheses are probably merely the manifestations of the behavior of the ductless glands.

140. **Operations to Restore Joint Functioning.**—Helferich has compiled about 300 cases of operations on joints with interposition of soft parts, not including twenty on the jaws. The results in this latter group have been constantly excellent. The method was applied to the elbow in 120 cases. Bier interposes a flap from the triceps or its tendon plus adjacent connective tissue; Lange used in two cases the brachial muscle with excellent outcome. Hoffa prefers a pedunculated flap of fat, while others take a loose flap. Putti has reported most excellent results in twelve cases with an interposed loose flap of fascia; the joint excursions run up to 120 or even 130 degrees in eleven old traumatic cases. All extol the advantages of the interposed flap. Helferich knows of only a very few cases in which the method has been applied to the shoulder, ankle, wrist, fingers or toes, but the results were good in nearly all.

The hip-joint has shown such excellent results from the method in the forty-nine cases in which it has been applied that one is amply justified in attacking a crippled hip-joint. Vulpius says that he has obtained his best results with the method in cases of ankylosis of the hip-joint, and points with pride to a case of total ankylosis of both hip-joints which he remedied completely. The patient can now, a year later, use the joint freely and flex the thigh at a right angle.

The knee is less amenable, and failures are comparatively frequent—though growing less so—but they are far outbalanced by such a case as Payr has described in which a cavalry officer was restored to active service when he was being compelled to resign on account of a stiff knee. Helferich has found records of seventy-five such operations on the knee. When the crippling is due merely to the patella growing to the femur, interposition of a soft-part flap naturally will remedy the condition. This was the first indication for which the method was devised, but it has been done as a separate operation only in eight cases to date. In conclusion Helferich protests against Murphy's remark that the technic for the nearthrosis operations requires a master's hand. Any trained surgeon can do it, and especially the younger surgeons will have gratifying success with it.

143. **Ear Symptom of Syphilis.**—This communication from Urbantschitsch's clinic at Vienna states that constitutional syphilis should be suspected, even when there are no other signs of it, when the ear is apparently otherwise normal and yet the Rinné test proves positive. He theorizes to explain the mechanism of the response. The familiar test is made by holding a vibrating tuning-fork opposite the opening into the ear and then transferring it to the mastoid process. Under normal conditions air conduction of the sound predominates over bone conduction; with morbid conditions in the nervous apparatus of the ear, air conduction predominates, but both are much briefer than in health. Beck applied the test to numbers of syphilitics whose ears and hearing were apparently entirely normal, and he found in 80 per cent. that bone conduction was materially shortened. This finding is characteristic also of conditions accompanied by increased intracranial pressure, and he thinks that this occurs probably also in constitutional syphilis, even before the syphilis induces symptoms.

157. **Atropin in Treatment of Dysmenorrhea.**—Novak found a history of painful menstruation in nearly every one of his cases of puerperal bradycardia and arhythmia. This suggested that the dysmenorrhea was traceable to the same cause as the other, and that it might be influenced by atropin, which has such prompt action on bradycardia due to abnormal irritability of the sympathetic nervous system. In small doses atropin has a stimulating and in large doses a paralyzing action on the sympathetic nervous system, and the few instances of failure to relieve the dysmenorrhea were probably due to incorrect dosage. The treatment was applied in large numbers of cases but only thirty-eight were followed for any length of time; thirty of the women were materially benefited by the atropin. The menstruation occurred without pain or so little that it was negligible. The predisposition to dysmenorrhea is either congenital or acquired, but the pains usually can be classed as (1) menstrual colic, possibly a kind of vascular crisis; (2) pains suggesting labor, due to clots or other abnormal contents in the uterus, or accumulation of blood with obstruction to evacuation, and (3) the pain from hyperemia—local congestion. Atropin arrests the pains by paralyzing the nerve terminals belonging to the vegetative nervous system. Novak's patients stated that the menstrual discharge increased in amount after taking the atropin, possibly from relaxing the spasmodic contraction of the vessels or of the uterus or both. Papaverin also has a paralyzing action on the smooth muscles, and may prove useful in combating dysmenorrhea. He expresses surprise that atropin has not been used more in gynecology as it seems so promising in this field, to ward off impending abortion, to relax painful stricture of the bladder sphincter or anus, or to keep the genital organs still and prevent ascending infection in case of local inflammatory processes. On account of danger of hemorrhage from atony of the uterus, atropin is necessarily contra-indicated when abortion or delivery is once under way and there is considerable uterine hemorrhage.

158. **Dangers of Combining Narcotics.**—Hinterstoisser states that considerable use is made in his service of the method of combining anesthetics and sedatives as a preliminary to and during operations, but he was recently startled by finding that one patient, a woman of 41, did not rouse after appendicectomy but lay in stupor for three days, with no control over bladder and rectum. Consciousness gradually returned the fourth day. He ascribes this prolonged stupor to the cumulative action of the drugs used, narcophin, scopolamin, ether, chloroform and morphin. Symptoms of severe intoxication followed the dose of morphin, cyanosis, respiration-rate only six or seven, then one or two to the minute, pulse slow but strong, the eye reflexes suspended. Artificial respiration was required for three hours. Then the paralysis of the respiration center was overcome by venesection and injection of Ringer's solution (withdrawing 300 c.c. blood and injecting a liter of the Ringer fluid). The woman began to breathe at once about sixteen times a minute, and the danger was over, although the deep somnolency continued for three more days. Brauer has recently reported a case of morphin poisoning in which no benefit was realized from venesection and saline infusion, and the patient was saved only by an emergency tracheotomy with oxygen supplied directly to the bronchi for several hours. The pulmotor failed to help in this case. Brauer ascribes the fatality in such cases not to the morphin but to the conditions which permit fatal intoxication of the respiration center by the carbon dioxid retained in excessive amounts owing to the deficient respiration for which the morphin is responsible. All the arguments thus sustain and explain the efficacy of venesection plus infusion of Ringer's fluid or isotonic salt solution.

162. **Cholera in Servia.**—Strisower reviews the experiences with 650 cases of cholera last summer, and bacteriologic examination of 2,000 persons. The mortality was from 41.4 to 42.9 per cent. irrespective of the treatment, but the 393 patients treated with potassium permanganate were all free from vibriones at the last examination, with four exceptions, while the proportion of carriers left after iodin, opium and quinin treatment was respectively 15, 75 and 10 per cent. One physician stated that he had had good results with yoghurt in convalescence from cholera. One epidemic broke out when a cavalry troop was quartered on a field where large numbers of soldiers had died of cholera and been buried several weeks before.

163. **Experimental Alcoholic Cirrhosis of the Liver.**—In the research reported 31 rabbits were given alcohol in various ways, injected intravenously or subcutaneously or poured through a tube into the stomach. The amount thus given the animals with an exclusively vegetable diet corresponded approximately to the daily ingestion by a man weighing 176 pounds of a quarter of a liter of 50 per cent. whisky, *Schnaps*. The longest period before the animal was killed was thirteen weeks. Among the 17 given the alcohol by the stomach, evidences of ulceration were found in 10. Signs of pronounced cirrhosis of the liver were found in all but 9 of the animals, and the testicles showed extreme atrophy. The histologic changes in the testicles resembled in every respect those found with chronic alcoholism, as reported by Simmonds, Kyrle, Weichselbaum and others. The fact of a predisposition to injury from alcohol is shown by the negative findings in 9 of the animals, although the conditions of the research had been identical for all.

164. **Radiotherapy of Trachoma.**—Rössler has been applying the Finsen method of treatment to trachomatous eyes, incited thereto by Groenholm's report of his unusual success with this treatment in trachoma. Rössler states that seventeen of the twenty-one thus "finsenized" were cured or materially improved, and in only four of the cases did the affection continue a progressive course. The cases of mild uncomplicated trachoma were the ones most benefited, and Rössler never witnessed such prompt and permanent cures under any other measures.

165. **Roentgen Treatment of Tuberculous Lymph-Nodes.**—Philipowicz says that his experience in twenty-five cases shows that the Roentgen ray is the most effectual of all measures in treatment of tuberculous lymphomas. The lymph-nodes subside in size under the exposures, he reiterates, the fistulas heal with a flexible cicatrix and the whole organism seems to be benefited while there are absolutely no subjective inconveniences. He gives the details of his twenty-five cases; three of the four given from 20 to 28 exposures are entirely cured and the fourth is nearly cured. All the twenty-five patients were materially improved, even those that had only a few exposures to date. The lymphomas responded alike whether they were still hard or had already softened. The sittings were for ten minutes, once in one or two weeks. No reaction on the part of the skin was ever noticed. About fifteen exposures are generally required. Danger of interfering with growth processes contra indicates Roentgen treatment under the age of 10, but this seems to be the only contra-indication.

166. **Chemical Bases for Treatment of Cancer.**—Until recently, Freund says, the why, whence and whither of cancer have been a sealed book to us, but experimental chemistry has lately shown that in cancer some normal element in the cell seems to have been used up and some foreign element has taken its place. This starts the cell to malignant proliferation or provides the soil on which something else is then able to accomplish this. This change in the cell has been rendered evident by recent biologic research which has shown among other things that the extract of tissues from certain points known to be a favorite developing point for cancer—such as gastric ulcer tissue—does not possess the normal tissue property of destroying cancer cells. This extract lacks the normal fat acids with which the normal cell protects itself against cancer. More than this, the intestinal content of a person with cancer—even when the cancer is not in the alimentary canal—does not contain the normal fat acids, but generates abnormal fat acids which induce in turn abnormal break-down

of albumin The abnormal products which result from this, act like a poison on the cells which are already suffering from the lack of the normal lipoids

The problem of cancer is thus transferred to the simple processes of tissue break down in the intestines, and these are to a certain extent under our control The task now before us is to study the conditions which favor the development of these baleful substances in the intestine content and means to prevent their production The effect realized can be estimated by determining the changes in the cancer cell destroying property of the serum A horse was immunized by injection of puncture fluid from a patient with cancer, and its serum, which at first destroyed cancer cells only at a 1 to 5 dilution, by the end of the year had acquired a destructive property in a 1 to 300 dilution Freund has no therapeutic results to report as yet, but is confident that the results of his research represent an important advance in our knowledge of cancer It points the way to neutralize with antibodies the cancer fostering substance, and to prevent its production in the intestines The substance in question seems to be a nucleoglobulin differing from ordinary nucleoglobulin *in that it contains more carbohydrate and fat acid*

169 **Gonorrheal Arthritis** —Tommasi has noticed that when gonorrheal arthritis develops he has always been able to find evidence of a preceding tuberculous infection, generally previously unsuspected until the thorough examination at this time reveals it He gives the details of twelve cases of the kind and also of an equal number of cases in which the tuberculosis was in a florid stage when the gonorrheal arthritis developed The tuberculin reaction he states, will be found positive in cases of gonorrheal arthritis, as a rule, and both the gonorrhea and the tuberculosis require treatment The serous membranes in the joints are less adapted to defend themselves against infection than others and, especially in latent, torpid tuberculosis, the joints are a point of lessened resistance

170 **Operation on Artery Instead of Vein for Varices** —Bondi argued that if the supply of blood to the varicose veins were cut down, the veins could take care of what did reach them, and the normal balance would be restored D Oria reports two cases in which treatment was applied on these principles a segment of the superficial femoral artery being cut out between two ligatures a short distance below the point where the deep femoral leaves the artery The patients were a man of 39 and a woman of 34, and both had long suffered from varices and edema of the left leg The small operative wound rapidly healed and all disturbances gradually subsided, leaving the patient entirely free from all varices and edema in that limb and the cure has persisted for three years to date in both cases In both instances the trouble in the vein was of thrombotic origin

ACCIDENTAL INJURIES TO THE DESCENDING PORTION OF THE DUODENUM DURING REMOVAL OF THE RIGHT KIDNEY

WILLIAM J. MAYO, M.D.
ROCHESTER, MINN.

The anatomic relations of the retroperitoneal portion of the duodenum are such that this organ may be injured during operations for the removal of the right kidney. Such injury, however, can only occur if there be infiltration about the pedicle which has caused close adhesion to the duodenum. The duodenum in its descending course overlies the pedicle of the right kidney and a considerable portion of the lower half of that organ on the inner side (Fig. 1). As this portion of the duodenum is retroperitoneal and more or less fixed in position one can readily understand how the accident might occur under such circumstances. The exact relationship of the duodenum to the right kidney depends on the mobility of the latter organ which lies somewhat lower than the left kidney and is more or less movable normally. The extent of this mobility depends on a number of factors. As shown by Harris,[1] the shape of the lower thorax, to a large extent, determines its position; a loose attachment of the ascending colon to the posterior parietes permits a wider range of motion. Under ordinary circumstances, during a right nephrectomy, the pedicle is loosened until it can be well surrounded with the fingers, clamped with forceps or tied, and as long as this method is followed the duodenum will not be injured. But in those cases in which, on account of infiltration, such a pedicle cannot be formed, it not infrequently happens that the vessels are torn with a resultant sudden gush of blood, or, after the removal of the kidney, the pedicle retracts from the forceps or ligature with sudden hemorrhage, necessitating active hemostasis. As shown by Gerster,[2] if the artery is cut first the veins may tear with consequent hemorrhage. In the effort to check this sudden hemorrhage by grasping the vessels with forceps having strong biting jaws and teeth at the end, the duodenum may be seized. As a rule, the injury to the duodenum is not manifested for several days. The injured part becomes necrotic and a duodenal fistula of a most distressing type results which will often, if not usually, cause the death of the patient.

I have known of three such injuries to the duodenum, the first many years ago when I was assisting a surgeon who was following a nephrotomy by a nephrectomy. Heavy biting forceps were left on the pedicle. On the fourth or fifth day a copious discharge began of biliary and pancreatic secretions, with food discharged almost as quickly as taken. The patient became rapidly exhausted and died in two weeks.

The second case was one of my own and the injury occurred in the removal of a carcinoma of the pelvis of the kidney, the result of a chronic irritation due to a large branched stone. The pedicle was extremely rigid from carcinomatous infiltration and in the attempt to remove it, the vessels were torn across in the infiltrated tissues. With considerable difficulty these vessels were caught by heavy, toothed forceps which were left *in situ*. On the fifth day a duodenal fistula showed itself. Biliary and pancreatic secretion and intestinal juices were passed in great quantities. The patient, already in a most serious condition, developed acute nephritis in the remaining kidney and died from asthenia on the tenth day. Necropsy showed a large fistulous opening in the descending portion of the duodenum.

The third case was one of duodenal fistula following nephrectomy seen in consultation. The pedicle had been infiltrated with inflammatory products, the kidney had torn loose. The injury to the duodenum was undoubtedly inflicted by the application of heavy forceps. In this case the fistula was small at first, but gradually increased in size, and the patient died two weeks after the operation. One feature in all these cases was the action on the skin of the escaping secretions. Large areas of the neighboring integument became scalded, painful and irritated. In one patient this set up a rapidly spreading eczema and in a week a great part of the skin of the body was affected.

From the fatal issue in these three cases, it would seem that accidental injury to the duodenum in connection with right nephrectomy is an exceedingly serious occurrence, and although after a somewhat careful examination of the literature, I have not found cases reported, I can only believe that this accident is more common than the records show, and that some of the cases in which fistulas have formed following right nephrectomy, while supposedly in other portions of the intestinal tract, have really been duodenal. It will be noted that in the three cases herein mentioned, duodenal injury took place during attempts to check hemorrhage, and probably all of them were due to forceps.

In this connection I would say that in the same manner the vena cava is even more frequently injured. When the pedicle is infiltrated, the renal veins may tear away from the vena cava and the latter be grasped in forceps in the attempt to stop the bleeding. On the left side the vena cava is not thus exposed to injury, since the veins are sufficiently long to cross the abdominal aorta to the left side of the body. Infiltration, either from infection or carcinoma, which causes a shortening of the pedicle containing the blood-vessels, makes the formation of an adequate stump difficult, and is the most common cause of the sudden hemorrhage which leads to the inaccurate use of the forceps and injury to the duodenum. Since the occurrence of the injury in the second case mentioned, I have tried to avoid the use of forceps in the first effort to control the bleeding from slipping of the ligature on the pedicle.

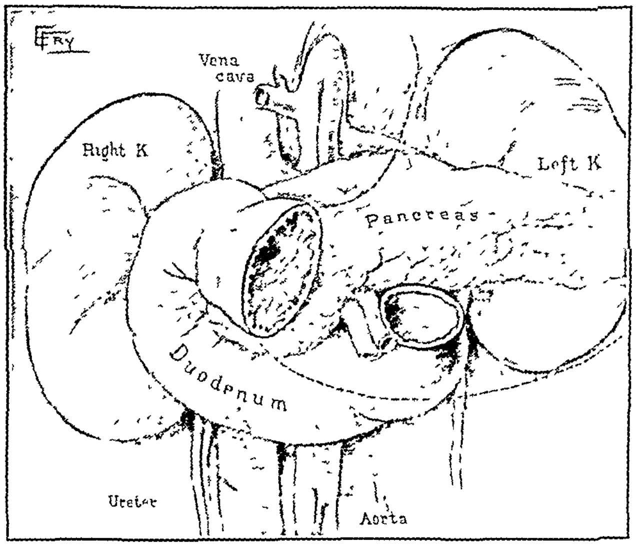

Fig 1.—Anatomic relation of duodenum to right kidney.

As a matter of fact, the use of forceps is seldom necessary for the immediate control of hemorrhage of this character. The fingers are so accurate and so sure a means of temporary hemostasis that they should be *depended on and the forceps used only to clamp the vessels after they are caught by the fingers.*

In vessels the size of the renals one has little difficulty in following the stream of blood directly to the pedicle and in its pulsation the artery fairly jumps into one's fingers. In these cases, the veins are usually tied to the artery by the infiltration and the whole pedicle can be thus secured with surprising ease. During the period in which an inadequate incision for nephrectomy was used I had the misfortune a number of times to lose control of the pedicle of the kidney during the enucleation, with sudden hemorrhage following, and never failed to grasp the vessels promptly with my fingers. This is quite true of other vessels of the same size. The larger the vessel, the more easily it can be grasped, as during systole the vessel is pushed forward.

In the removal of large pelvic tumors and rectosigmoidal carcinomas, I have, on several occasions, had a torn or divided internal iliac to deal with, and was always able, even with the hand deep under the tumor, to grasp and hold the vessels until the tumor could be removed and the arteries and veins accurately secured. With an adequate incision for the removal of the kidney, such as I have previously described,[3, 4] injuries to the duodenum or failure accurately to secure the vessels will seldom occur. Division of the structures behind the twelfth rib combined with transverse incision (Fig. 2) mobilizes the lower wall of the chest, and with the patient lying on the loin of the opposite side, well elevated in a saddle, nephrectomy has been made a safe procedure, because it is done under the eye.

In two classes of cases, however, injuries to the duodenum as well as the vena cava are liable to occur. When fixation and shortening of the pedicle takes place as the result of inflammation, usually in cases of pyonephrosis with stone and especially following nephrotomy for such a condition, the attempt to remove the kidney in the ordinary manner renders accidents in securing the pedicle not infrequent. Nephrectomy secondary to nephrotomy, especially when complicated by fistulas, are notoriously difficult. In Tuffier's clinic nearly fifteen years ago, I first observed such cases handled properly; that is, by means of a subcapsular nephrectomy. If the disease for which the kidney is to be removed is neither malignant nor due to tuberculosis or other disease which requires removal of the capsule, it is comparatively easy and safe to continue the outer incision into the fatty and fibrous capsule of the kidney and then to enucleate the entire kidney from its bed in the firm surrounding wall, securing the pedicle in the hilum of the kidney itself. Under such circumstances, it may occasionally happen that the kidney will be completely separated before the pedicle is secured, and there may be little hemorrhage from the vessels at the point where they have pulled off. If severe hemorrhage does occur, the firm rigid cavity lends itself to the control of the bleeding on pressure either by the fingers or a piece of gauze held in the fingers. By sliding the fingers from below up, the mouths of the vessels can readily be seen and controlled with forceps or suture. Were one working outside this firm capsule, no such control could be exercised over the vessels, which would promptly retract, adding to the difficulty of securing them. When there is much infiltration and subcapsular nephrectomy is not advisable, the peritoneal cavity and sometimes the

pleura may be opened. It is always necessary, therefore, after separating the kidney, but before its removal with possible soiling of the field, to examine carefully to see that there is no opening into the peritoneum. The pleural cavity, which fortunately is very rarely injured, makes itself manifest by a sibilant sound when the air rushes in and out during respiration so that this injury is not liable to be overlooked.

The kidney is held in position, first, by its fatty capsule, second, by the ureter and third, by the blood-vessels. In doing nephrectomy, the separation should be made in the following sequence: the kidney loosened from its bed until it is held only by the vessels and the ureter, the ureter then pulled to the surface, caught between two clamps, sterilized with phenol (carbolic acid) and both sides tied. The clamp is not to be left on the side of the kidney, since it may be pulled off during the further course of the operation with soiling of the field. By thorough separation of the perirenal adhesions, the vascular pedicle can, as a rule, be easily secured in a small mass.

In the removal of carcinoma of the pelvis of the kidney, injuries to the duodenum and vena cava are most liable to occur. The most frequent malignant tumor of the secreting structure of the kidney of the adult is the so-called hypernephroma, more properly termed "renal mesothelioma," as pointed out by Wilson.[5] We should remember that the kidney is formed from two entirely separate anlages. For a long time it was thought that the entire kidney was formed from a diverticulum from the wolffian duct. It is now known that only the ureter, pelvis, calices and straight tubules are so formed. That is, only that part of the kidney which collects the urine has its origin in the wolffian duct. The secreting structure of the kidney has a far different origin in the nephrogenic tissue, which is mesothelial in origin. Therefore, we have two entirely different types of malignant disease of the kidney, one having its origin in epithelial structures, a true carcinoma, and the other arising in mesothelial tissue, which has been incorrectly termed hypernephroma, a malignant disease of the secreting structure of the kidney which has some general similarity in morphology to tumors of the adrenal body. Grawitz,[6] in 1883, first called attention to the resemblance between these growths and the adrenal body and under his influence these tumors were called hypernephromas. Stoerk[7] and Wilson[5] have shown, however, that the adrenal body is formed in what is later to become the pleural cavity, and that it is always separated from the kidney by a complete histologic membrane, and, further, that these so-called hypernephromas always occur in the renal substance and not in the fibrous capsule of the kidney where such supposed adrenal remnants are most frequently found; also, that such tumors are rarely found in the adrenal body itself and when so found give an entirely different picture clinically and pathologically from the ordinary tumors in the kidney which have been called hypernephroma. That true hypernephromas or tumors of the adrenal body and of adrenal rests in the kidney may be found there is no question, but they are extremely rare. It now seems proved beyond reasonable question that the so-called hypernephroma of the kidney is, in most instances, mesothelial in its origin, and, unlike carcinoma, seldom involves the glands until very late, but tends to spread by means of the blood-stream as would be expected in tissue so closely related to the connective-tissue group. Nephrectomy for large tumors of this description is usually best accomplished by some type of transperitoneal incision, because the tumor presents anteriorly, crowding into the abdominal cavity. The incision outlined in Figure 2 can be brought well forward toward the median line, and, if necessary, supplemented by a straight incision in the right rectus muscle, or a long transperitoneal incision at the outer border of the rectus muscle will be found satisfactory. The ascending colon is separated and drawn to the inner side. The ureter is double tied in its course and cut between. The lower portion of the growth is separated on its inner side and the upper fragment of the ureter followed to the renal artery and vein. These vessels are dissected out, tied and divided before the growth is removed from its bed.

During the removal of renal mesotheliomas, accidental injury to the duodenum will not often take place, because the pelvis is seldom involved in the disease. But when we come to the group of carcinomas, true epithelial proliferation which involves the pelvis, the calices and other structures having origin in the wolffian duct, an entirely different picture is produced. In 85 per cent. of our cases this type of cancer was the apparent result of a chronic irritation from stones in the renal pelvis. Here infection and ulceration of the pelvis and secondary involvement of the connective tissue in the pedicle leads to fixation and shortening of the pedicle together with adhesion to the neighboring viscera on the right side, and sometimes to the duodenum in its retroperitoneal portion. In such cases, subcapsular nephrectomy is inadequate if we are to give the patient a chance for cure. The kidney and capsule, with the pelvis and an adequate portion of the ureter must be removed, and it is in these cases that the duodenum will be endangered even by the most expert and careful surgery.

When this accident occurs, what can be done to repair the damage? Here is the crux of the problem. As a rule, the duodenal injury is not made manifest until several days after the operation. The character of the fistula does not lend itself to spontaneous healing, the gastric, intestinal, pancreatic and biliary secretions in combination rapidly enlarge the opening, irritate the skin and exhaust the patient. As shown in the post-mortem in the second case mentioned, the fistula was large, infiltrated and, of course, without peritoneum. In a similar case I should, before the patient became exhausted, make a transperitoneal attack on the fistula itself, lift the descending duodenum from its bed, suture the opening, transplant a flap of peritoneum or omentum across the suture line and finally make a jejunostomy for temporary feeding purposes. It does not take much imagination to suggest and draw on paper various methods of multiple short-circuiting operations, but at the operating-table with the patient in the condition which would probably exist under such circumstances, the carrying out of such schemes would be sufficiently uncertain to make us careful to avoid the accident.

In the Cause of Medical History.—Anything that will, so to speak, humanize our art and science, will not only make us happier, but more satisfied with and proud of our profession and its aims, more inspiring to our students, better friends and helpers to our patients. With history as helpmate we apply "not the experience of one man only or one generation, but the accumulated experience of all mankind in all ages," to use John Herschel's phrase.—Klebs in Bull. Johns Hopkins Hosp.

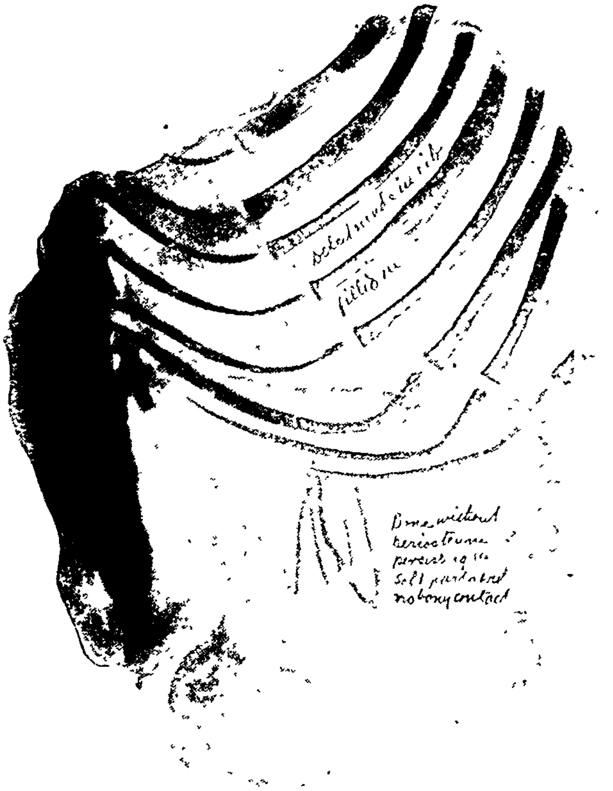
THE PERIOSTEUM IN BONE TRANSPLANTATIONS

IS CONTACT WITH LIVING BONE NECESSARY FOR THE LIFE OF GRAFTS, AND WILL TRANSPLANTED PERIOSTEUM PRODUCE NEW BONE? *

CLARENCE A. McWILLIAMS, M.D.
NEW YORK

Experiments were undertaken to determine, if possible, answers to the above questions. A distinguished authority, Dr. John B. Murphy, has maintained that contact with living bone is absolutely and unconditionally necessary for the subsequent life of grafts. Thus, he expresses himself[1] as follows:

> In bone transplantations, there is but one absolute essential, other than rigid asepsis, and that is that the bone graft must be closely connected at some one point at least with living, freshened, osteogenetic tissue. Also[2] he says: Bone with or without its periosteum, transplanted into the muscle or cellular tissue, practically always dies and is absorbed, when it is free from bony contact.



Defect made in rib
filled in
Bone without periosteum persists in soft parts and no bony contact

Fig. 1.—Difference between the reformation of the rib when the periosteum is left and when it is removed (Experiment 1). Above, defect in rib filled in; below, bone without periosteum persisting in soft parts with no bony contact.

No proofs, however, were forthcoming to substantiate this conclusion, and it was with the object of helping to decide this question that the following experiments were performed. Figure 1 proves that strips and fragments of bone without periosteum, transplanted into the soft parts, not in contact with living bone, may remain living. This is confirmed by photomicrographs. In Figure 2, one fibula strip without periosteum, which was in contact with living bone (the last rib), is shown to have become absorbed, leaving the three other fibula strips without living bone contact, yet alive and active. In Figure 3, the two ribs with periosteum are shown to have lost their contact with the living last rib, yet, notwithstanding, they both remain perfectly alive. In Figure 4, it may be seen that the left fibula *B* with periosteum, transplanted into the soft parts of the right leg and not in contact with living bone, remains beautifully alive. Figure 5 shows that the left fibula *B*, with periosteum into the soft parts of the right leg, not in contact with living bone, has proliferated to at least three times its normal size. It is very actively alive. Figures 6, 7 and 8 are roentgenograms of a human transplantation in which a fracture of the graft took place and the way new bone developed about this fracture, to my mind, does away with the idea that contact with other living bone has much to do with the life of grafts.

Conversely, I am prepared to show that even with this contact with living bone, grafts without periosteum may not live. Murphy[3] says:

> Bone with or without periosteum, transplanted in the same individual and contacted with other living osteogenetic bone at one or both of the ends of the transplanted fragment always becomes united to the living fragments and acts as a scaffolding for the reproduction of new bone of the same size and shape as the transplanted fragment, if asepsis is attained.

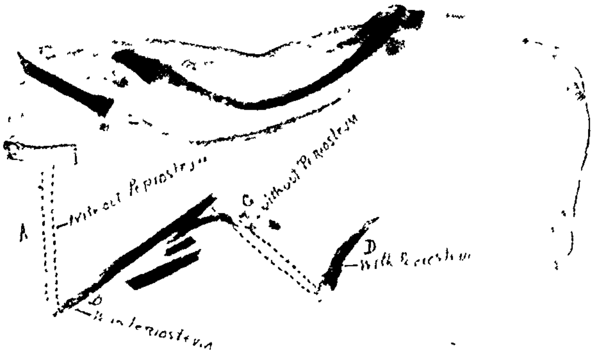


Fig. 2.—Uncertainty of grafts without periosteum (Experiment 3): *A*, strip without periosteum, entirely absorbed; *B*, strip with periosteum alive; *C*, strip without periosteum broken up into six pieces displaced upward; *D*, strip with periosteum alive with production of new bone.

No definite proof has been forthcoming as to the truth of this statement. I have gone all through Dr. Murphy's reported transplantations and find that in not a single instance has he made a transplantation without periosteum being on the transplant. Contact with living bone with Murphy is the keynote of success. To my mind he has overlooked the most important point in bone-grafting, namely, the periosteum. Thus, Figure 9 shows that fragments from the right fibula transplanted into the left fibula defect without periosteum, although in contact with the living stumps *A* and *B*, have entirely disappeared, while those fragments into the right fibula defect from the left fibula with periosteum have remained living beautifully. Contact with the living stumps certainly can have had very little to do with the life of the fragments in the center of the right leg transplant. Another roentgenogram showed the same result in an exactly similar operation with the exception that the fragments in the right leg with periosteum have taken on enormous growth, and who will say that contact with living bone has had any influence on the production of new bone in the central section of the transplanted fragments in the right leg of Figure 9?

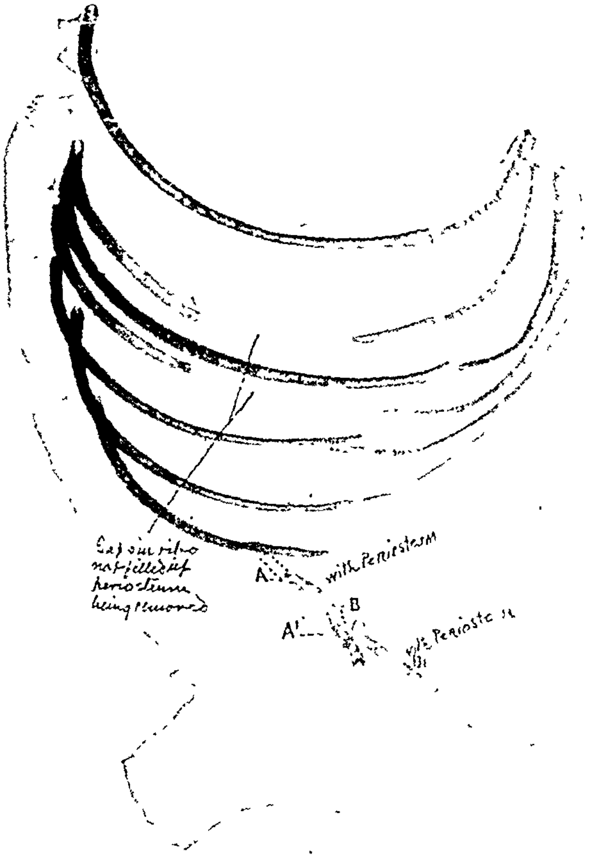

Fig. 3.—Transplantation of ribs (Experiment 4). Gaps in ribs not filled up, periosteum being removed; A, transplant fractured into two pieces, A¹ being the second and lower piece of A; B, second grafted rib (with periosteum) likewise fractured, B being the small upper part of Bi.

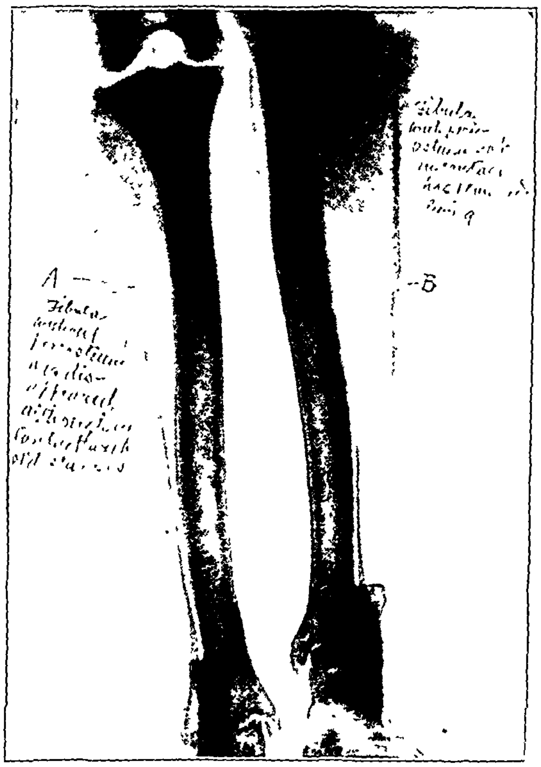
Again, in Figure 4 the right fibula without periosteum *A*, transplanted into the left fibula defect, is shown to have almost entirely disappeared, although this fibula was in contact with the living stumps, while the left fibula with periosteum *B*, grafted into the right fibula defect, yet not in contact with living bone, has remained living. Exactly the same thing is shown to have occurred in Figure 5, *A* being the position in the left leg of the transplanted right fibula without periosteum. This has entirely disappeared, while *B* is the left fibula with periosteum, not in contact with living bone, transplanted into the right defect. It has grown and enlarged markedly.

Murphy, Albee and others have had practically 100 per cent. of successes with grafts made with periosteum. My experience is the same, except that I have had one human transplantation with periosteum which became infected, necessitating the removal of the graft, which should not count in the result, and one animal experiment in which the graft made with periosteum disappeared. I have had 87 per cent. of successes with periosteum on grafts (sixteen cases).

On the other hand, I have had twenty-five transplantations without periosteum, and of these but 48 per cent. succeeded, although there was primary union in all. How can one escape the conclusion that periosteum, next to asepsis, is the important factor in making for success in bone-grafting? There may be some uncertainty as to just how the periosteum acts, but of its importance there can be no doubt. My conclusion is that it acts by affecting the blood-supply to the grafts and that its osteogenetic function is of secondary importance, else why did 48 per cent. of the grafts without periosteum succeed? The answer, it seems to me, is that the blood-supply of the 48 per cent. of successful grafts without periosteum was sufficient to keep them alive, while in 52 per cent. it was insufficient, and hence the grafts died.

REPORTS OF EXPERIMENTS

EXPERIMENT 1 (Dog 172).—This dog was killed eight months after the operation. This experiment, in the first place, indicates the difference between the reformation of the rib when the periosteum is left and when it is removed. The rib in this dog was subperiosteally removed. It has entirely reformed (Fig. 1). The rib without periosteum was split into longitudinal strips which were transplanted under the rectus sheath of the abdomen. These strips have grown together and they show no evidence of any absorption, not being honeycombed at all. This I attribute to the fact that the splitting of the rib allowed a sufficient blood-supply to get to the bone-cells so that they remained alive. This and the following experiment are a refutation of Dr. Murphy's statement that a bone-graft, with or without periosteum, when transplanted into the soft parts and not in contact with living bone, always becomes absorbed.



Fibula with periosteum not in contact has grown
A
Fibula without periosteum has disappeared although in contact with old stumps
B

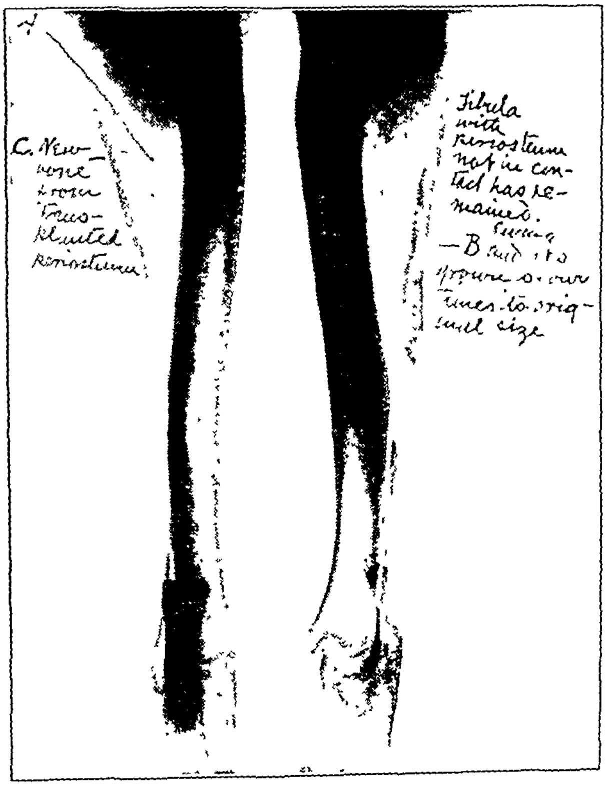
Fig 4.—Difference made by presence or absence of periosteum (Experiment 4); *A*, fibula without periosteum has disappeared, although in contact with old stumps; *B*, fibula with periosteum, though not in contact, has remained living.

A photomicrograph of a section of the abdominal transplant shows that the fragment of bone measures 0.2 cm. in diameter. The bone contains many cells with well-preserved nuclei, and also perfect haversian canals with red blood-cells within them. The bone itself is intact. There are several osteoclasts within lacunae on the margin of the fragment. Many osteoblasts are also present. The marrow is well preserved and contains blood-spaces, many of them filled with red blood-cells. Because of the osteoclasts, there are present destructive processes, but at the same time proliferation is also in progress. The bone seems to be perfectly alive.

Experiment 2 (Dog 19).—The dog was killed six months after subperiosteal resections of two ribs. One rib had entirely reformed while the other had not quite completely filled in the defect. The ribs without periosteum were broken up into the smallest possible fragments and these were transplanted into the abdomen lying on the muscle. A roentgenogram showed that the fragments had grown together and increased in size. There was no sign of any absorption.

A photomicrograph of a section of the bone in the abdomen shows a fragment, measuring 2 by 0.3 cm. This bone fragment is enclosed in a dense connective-tissue enveloping capsule. There are many osteoblasts present both on the trabeculae within the bone-spaces and also on the periphery of the fragment, especially at either end. There are many well-formed blood-vessels present in the haversian canals. The marrow and adult fat within the bone spaces also support many blood-vessels, having well-formed walls. The red blood-cells in these blood-spaces are well preserved and distinct. The bone-cells are normal in appearance and their nuclei stain distinctly. There are no signs of degeneration or destructive process present in the sections, which seem perfectly alive.

Experiments 1 and 2 clearly demonstrate that the life of a living graft depends solely and entirely on a sufficient blood-supply. The large grafts were each broken up into smaller pieces, so that blood had easy access to their cells, and hence the grafts lived and increased in size, notwithstanding the fact that there was no periosteum attached to them and that they were not in contact with living bone. My human cases demonstrate the fact that large grafts without the periosteum may die, and I infer from this that the blood-supply to the large grafts is insufficient to keep them alive. Since, if the periosteum be left attached, the graft may not die, the soft and porous structure (as compared with bone) of the periosteum permits it to get its blood-supply from the surrounding tissues, and from this the bone is reformed.



A
C. New bone from Trans-planted periosteum
Fibula with periosteum not in contact has remained.
—B living and its grown four times to orig-inal size

Fig. 5.—Bone transplantations with and without periosteum; *A*, piece of fibula without periosteum has entirely disappeared; *B*, fibula with periosteum not in contact has remained living and has grown to four times its original size; *C*, new bone from transplanted periosteum.

Experiment 3 (Dog 363).—Two-thirds of each fibula were resected with their entire periosteum. Each fibula was split into two pieces, making four sections in all. From two of these pieces the periosteum was removed, while the other two were transplanted with their periosteum still attached. The external oblique of the left side was dissected up, just below the last rib, whose periosteum was split and separated from the bone. One of the four strips (without periosteum) was sutured to this bared area of the last rib. To the end of the first strip was sutured a second strip of fibula with periosteum on half its surface. To the end of the second piece of bone was sutured a third strip of fibula without periosteum on any of its surfaces, and to the end of the third piece was sutured the fourth strip of fibula with periosteum on half its surface.

Result.—The defects made in the fibulae have not been filled in with new bone in the slightest, 108 days after operation. The strip *A* (Fig. 2) without periosteum has been entirely absorbed. The strip *B* with periosteum remainst perfectly alive and shows no signs of any absorption. The strip *C* without periosteum has become broken up into six pieces, which have become displaced upward. All these irregular pieces look alive. The strip *D* with periosteum is alive and its irregularities show that it has produced new bone.

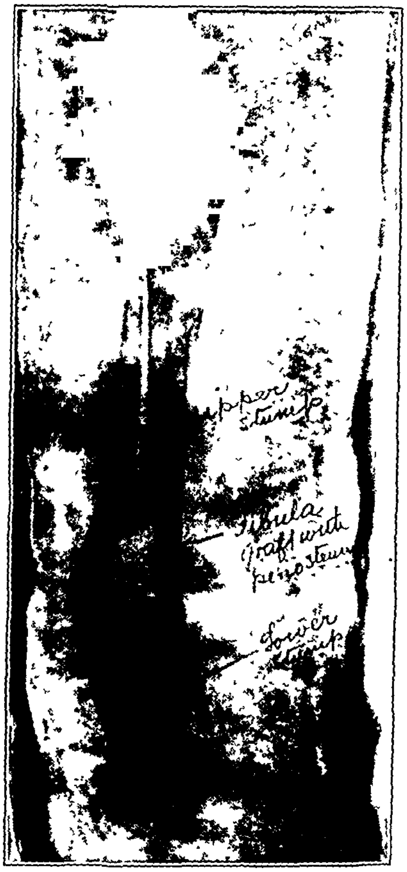


Fig. 6.—Five inches of the opposite, healthy fibula, transplanted into the medullary cavities of the stumps of the old tibia, in a child.

This experiment demonstrates that without periosteum there is always uncertainty as to what a graft without it will ultimately do. In some cases the bone will remain living, in other instances it will become absorbed, in other cases it will break up into small pieces, all of which goes to show that the question of blood-supply is the all-important factor. With periosteum we are sure of the grafts living.

Experiment 4 (Dog 220).—Two inches were excised from two ribs with their entire periosteum on all sides. The last rib was bared, the external oblique split. The last rib was separated from its periosteum for a short distance, and to this bared area was sutured one end of one of the ribs with its periosteum on all sides intact. To the other end of the transplanted rib was sutured one end of the second rib with periosteum on all its sides, by drill-holes in the two extremities. The two ribs were then transplanted between the external and internal oblique muscles.

Result.—The defects in the two ribs have not in the slightest become filled in with new bone, 112 days after operation. This is probably due to the fact that there was no channel left between the ends. The transplant A (Fig. 3), has become fractured in two pieces, A¹ being the second and lower piece of A. Both these pieces are undoubtedly alive. The upper part of A has become displaced from the last rib. This is another demonstration of the fact that grafts do not need to be in contact with living bone in order to remain living, contrary to Dr. Murphy's teaching. The second grafted rib Bi (with periosteum) has likewise become fractured, B being the small upper part of Bi. The entire graft B likewise remains living, although it is not in contact with living bone.

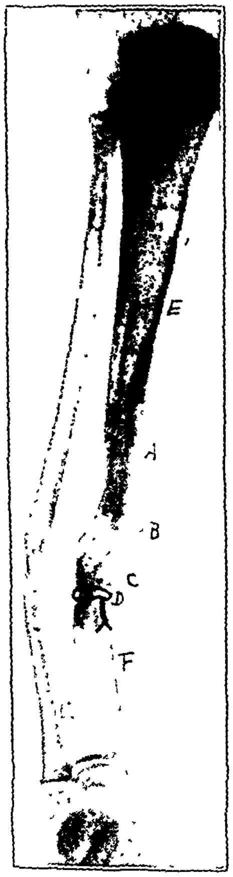

Fig. 7.—Seven months after the grafting operation in the same patient as in Figure 6; *A*, new bone; *B*, callus; *C*, fracture which occurred two months after the operation; *D*, lower fragment of the graft; *E*, *F*, ends of the old bone of the upper and lower stumps.

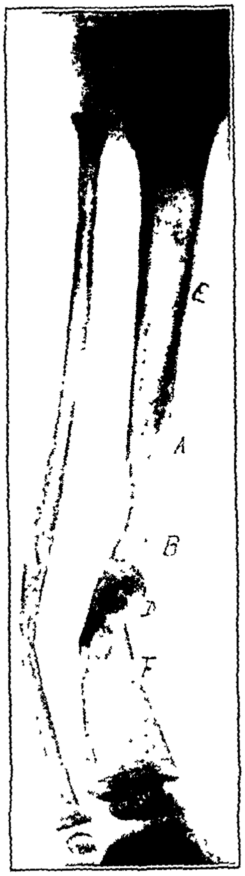

Fig. 8.—Three months after the removal of the wire strand shown in Figures 6 and 7, ten months after the original grafting operation; *A*, new bone; *B*, callus; *D*, lower fragment of graft; *E*, *F*, ends of the old bone of the upper and lower stumps.

Experiment 5 (Dog 423).—A section from the right fibula intact without periosteum was transplanted into a left fibula defect in contact with old stumps. The stumps of the right fibula defect were covered with muscle which was sutured over them. The entire section from the left fibula with the periosteum still on it uninjured, was placed under the fascia of the right leg.

Result.—Eighty-one days after the operation, the section into the left fibula defect without periosteum has almost completely disappeared (*A*, Fig. 4). There is a slight line left indicating a persistence of some of it. This disappearance has occurred notwithstanding that it was in contact at both ends with living bone. The difference the presence or absence of the periosteum makes is indicated in the right leg. The section from the left fibula into the right fibula defect with periosteum has remained of its original size and seems perfectly alive (*B*, Fig. 4), notwithstanding that it was not in contact with living bone. This experiment is another evidence that Murphy is mistaken in his statement that grafts must be in contact with living bone *in order to live*. This experiment would also seem to indicate that the periosteum is the important element in maintaining the life of grafts, owing probably to its influencing favorably the blood-supply.

Experiment 6 (Dog 426).—Sections from each fibula were excised. From the section from the right side all the periosteum was bluntly stripped off from all its sides in one place. This strip of periosteum *C* was vertically stretched out under the skin of the left leg. The bone itself from the right fibula without periosteum, *A*, was placed in contact with the ends of the old stumps in the left fibula defect. Over the ends of the stumps of the right defect in the fibula, muscle was sutured so that the graft would not be in contact with living bone, and the section *B* from the left fibula with its periosteum entire was placed in the superficial muscles of the right leg. The section of bone with periosteum in right leg, *B*, not in contact with living bone, has grown to two or three times its normal size and is certainly perfectly alive.

Result.—One hundred and two days after operation (Fig. 5), The piece of fibula *A* without periosteum from right fibula into left defect has entirely disappeared. This is probably due to the fact that the bone was transplanted entire. Had it been split as in the first two experiments it is possible that it would have survived, owing to the consequent better blood-supply. The periosteum, *C*, on the other hand, transplanted under the skin of the left leg, has developed a new mass of bone of the size and shape of the old fibula from which it was taken.

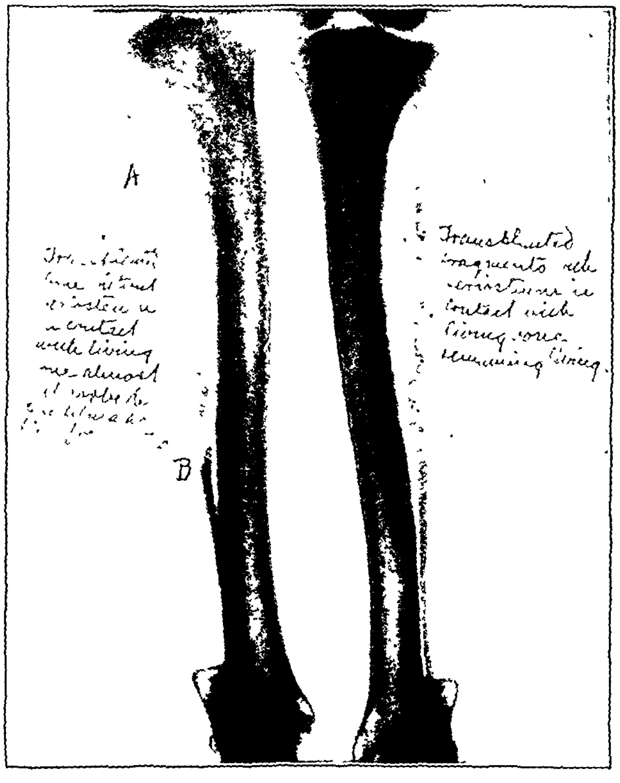

Fig. 9.—Transplantations with and without periosteum (Experiment 7); left fibula defect, *A*, *B*, transplanted bone without periosteum in contact with living bone almost absorbed; the fibula was first fragmented; right fibula defect, transplanted fragments with periosteum in contact with living bone remaining living.

Figures 6, 7 and 8 are roentgenograms of the same human transplantation, in which a defect in the tibia had to be supplied by a graft. In Figure 6 we see 5 inches of the opposite, healthy fibula transplanted into the medullary cavities of the stumps of the old tibia. The lower extremity of the graft was held in place by an encircling wire strand. Periosteum covered the graft on all its sides and this was unsplit. Figure 7 was taken seven months after the grafting. A fracture took place in the graft about two months after the operation, owing to the child kicking off the splint one night. In Figure 7 we see what an enormous callus, *B*, developed just above the fracture. I do not wish to be too dogmatic about where the new bone of the shaft *A* and that of the callus *B* came from, but I unhesitatingly think that this new bone is derived either from the periosteum itself or else from the bone-cells of the graft itself. Were it derived from the ends *E* and *F* of the old bone of the upper and lower stumps, it seems to me that it would shade off the farther we went from the ends of the old stumps, being greatest in amount near the old bone and shading off to become less and less the farther we went from the stumps. As a matter of fact, the greatest amount of new bone is at the fracture spot in the graft, which is some distance from either end of the stumps. The lower fragment, *D*, of the graft has not developed proportionately, owing to the inhibitory influence of the wire strand, which is eroding the fragment. This wire was then removed. Figure 8 was taken three months after the removal of the wire strand, and ten months after the original grafting operation. The lower fragment, *D*, has developed greatly, the furrow made by the wire being more than completely filled in by new bone. The fracture is consolidating nicely. That the bone of the lower fragment, *D*, has a life independent of the lower stump, *F*, is indicated by the lower stump, *F*. It is clearly seen that *D* is uniting to the lower stump *F*, and also to the graft *B* by life inherent in itself. The callus, *B*, is much smaller in Figure 8 than in Figure 7

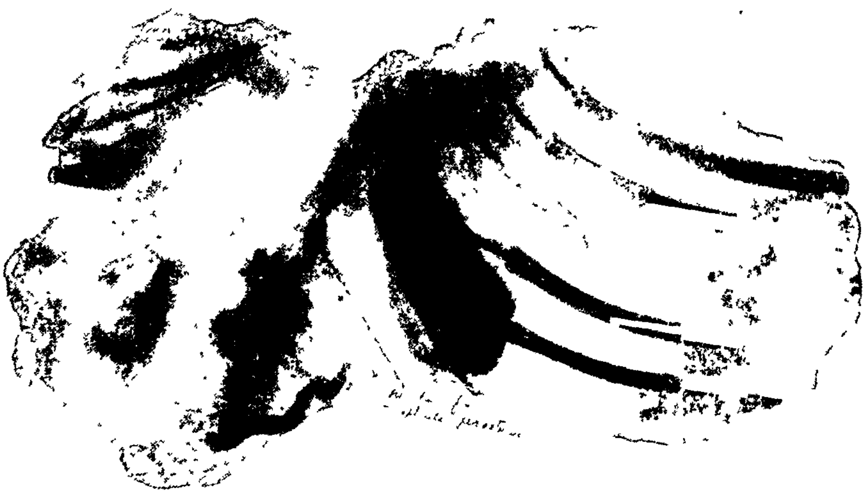

Fig. 10.—New bone from transplanted periosteum (Experiment 9).

EXPERIMENT 7 (Dog 293).—Figure 9 was taken nine months after the transplantation, in which a segment from the left fibula was divided into as small fragments as possible, with the periosteum left attached to each fragment, and these fragments were transplanted into the right fibula defect in contact with the stumps of the fibula. Into the left fibula defect were transplanted fragments from the right fibula from which all the periosteum was scraped.

Result.—The fragments into the left fibula defect *A* (without periosteum) have almost completely disappeared. The fragments are few in number, isolated, not united, and they look as though they were becoming absorbed, being much reduced in size. In contrast to these, the fragments transplanted into the right fibula defect (with periosteum), have in most places become united to each other, show no diminution in size and cause healthy shadows. It seems evident that there was not supplied enough blood to the left fragments without periosteum to keep them alive. This picture is another evidence of the value of the periosteum and is another proof of the fact that contact with living bone is not the important element which Dr. Murphy has attributed to it, and demonstrates the value of the periosteum.

EXPERIMENT 8 (Dog 309).—Fragments from a section of the right fibula from which all the periosteum was thoroughly scraped, were grafted into a defect made in the left fibula. Fragments with periosteum still attached to them, taken from a section of the left fibula, were transplanted into the right fibula defect.

Result After Eight Months.—The fragments into the left fibula defect without periosteum have entirely disappeared. The pieces into the right fibula defect with periosteum have markedly increased in size and have largely united to each other. This case illustrates the value of the periosteum on grafts in case there is a deficiency in the blood-supply. The feature to be particularly emphasized in this experiment is the pronounced increase in the size of the grafts with periosteum on them transplanted into the right defect, which denotes an active life in the grafts; also the fact that, although the middle section of the right-sided graft does not seem to be firmly united to the neighboring grafts, yet this middle section, from its deep shadow, appears to be as actively alive as the sections which are in intimate contact with the ends of the old stumps, all of which still further goes to show that contact with living

Fig. 11.—Transplantation of fibula sections without periosteum and transplantation of periosteum (Experiment 10); *A*, right fibula without periosteum has remained living; *B*, left fibula transplanted without periosteum has remained living; *C*, new bone from transplanted periosteum.

old bone has not the important influence on the subsequent life of grafts which Dr. Murphy has attributed to it.

EXPERIMENT 9, Figure 10.—This animal was killed six months after the operation. The removal of a section of a rib with its attached periosteum shows no reformation of the rib. The periosteum was stripped off the section of rib bluntly and this sheet was planted between the rectus muscle of the abdomen and its posterior sheath.

Result.—On cross-section six months later, this transplanted periosteum cuts as hard as bone and with the same sensation (Fig. 10). A photomicrograph of a section of this new bone from the periosteum shows that there is a distinct mass of bone, measuring 0.8 by 0.2 cm., which is enclosed in a definite connective-tissue capsule. The bone itself contains cells, the nuclei of which stain deeply with hematoxylin. At points on the periphery of the bone there are osteoblasts. In the actual bone substance itself there are haversian canals which contain blood-vessels the size of large arterioles. Within the bone trabeculae there are adult fat- and marrow-cells, and the whole presents a normal appearance. There are many blood-spaces in the marrow and these spaces are supported by a definite connective-tissue stroma. The red blood-cells in these blood-spaces, while not sharp and distinct in outline, are not degenerated. There are no osteoclasts or round cells present, suggestive of either a destructive process or one of inflammation. The bone is alive and the periosteum has reformed a normal rib.

EXPERIMENT 10 (Dog 374).—From each fibula 2½ inches were resected. The periosteum was removed from each *in toto.* The periosteum from the right fibula section was a beautiful sheet, removed without scraping, by stripping it off the bone bluntly. This was transplanted just under skin of the left leg, lying on the muscle. The periosteum from the left fibula section was a frayed-out strip which was scraped off with a knife. This was transplanted under the skin of the right leg. The right fibula section without periosteum was transplanted into the left fibula defect and the left fibula section without periosteum was transplanted into the right defect.

Result.—After 142 days each fibula section without periosteum has remained living perfectly. That transplanted periosteum may produce bone is here again demonstrated. The perfect sheet of periosteum transplanted into the left leg has produced a fine piece of bone, while the frayed-out piece of periosteum into the right leg has produced just a suspicion of new bone (Fig. 11). This indicates that the periosteum is a delicate structure. It is worthy of remark that the periosteum into the left leg was removed bluntly by tearing it off the bone and was not obtained by scraping it off with a knife, which procedure would carry off with the periosteum some of the superficial bone-cells.

WILL TRANSPLANTED PERIOSTEUM PRODUCE NEW BONE?

There have been various answers to this question. Macewen has minimized the importance of the periosteum when he says that it acts merely as "a limiting and protecting membrane and has no osteogenetic function." He has not found that it produced new bone when it is raised up in strips from the bone. I have found that new bone would develop about transplanted periosteum in about one-quarter of the cases in which it was transplanted alone. Thus, in Figure 10, the periosteum from a rib, transplanted into the abdomen, has produced new bone. Also in Figure 5, a fine growth of bone, *C,* is seen to have developed about the transplanted periosteum. Likewise in Figure 11, new bone, *C,* has developed about the transplanted periosteum. In many cases I believe that the periosteum is so greatly damaged in separating it from the bone that it will not produce bone. To my mind the question of whether or not periosteum will produce new bone when it is transplanted alone into the soft parts is beside the mark and of little importance, because, as I believe, the function of the periosteum is to maintain the nutrition of the grafts quite aside from any osteogenetic function that it may have.

CONCLUSIONS

1. The theory that contact with living bone is necessary for the subsequent life of grafts must be given up.

2. Living bone-grafts have life inherent in themselves and are capable of permanent growth even when transplanted into the soft parts.

3. The life of grafts is dependent on a sufficient blood-supply. This is surely obtained when periosteum is on the grafts, since practically 100 per cent. of such grafts are successful, whether the transplants be in contact with living bone or not, or whether they be grafted into the soft parts and not in contact with living bone.

4. Forty-eight per cent. of my bone grafts without periosteum were successful whether contact with living bone was made or not. This goes to show that there is some other factor present making for the life of grafts than the periosteum or contact with living bone, and this I take to be a sufficient blood-supply. It is therefore evident that the periosteum has a deciding influence in favoring a good blood-supply with its consequent subsequent life of the grafts. Since it is impossible to tell beforehand when grafts without periosteum will attain this sufficient blood-supply, the lesson is evident that grafts should always be transplanted with as much of their attached periosteum as possible.

5. Periosteum transplanted into the soft parts will produce new bone in a certain proportion of cases.

EPIDIDYMOTOMY

WITH REPORT OF CASES

CARLISLE P. KNIGHT, M.D.
Assistant Surgeon, United States Public Health Service
STAPLETON, N. Y.

Excellent success and most gratifying results have been obtained at the United States Marine Hospital, Stapleton, N. Y., with Eckels' operation for epididymitis. The technic described by Eckels,[1] except for slight modifications, has been followed.

In the operation, as I have performed it, an incision is made in the scrotum about 1½ inches below the lower border of the external ring and is prolonged far enough to allow free delivery of the testicle with the tunica vaginalis. The organ is then wrapped in sterile cloths moistened in warm saline solution, and a small incision is made in the tunica vaginalis which allows any fluid present to escape. The epididymis is next exposed and that portion which appears inflamed is punctured in several places. This relieves the tension by allowing the restricted fluid to escape. Eckels states that for puncturing the epididymis he uses a blunt probe or grooved director. I employ a large blunt-pointed needle, making from ten to twelve punctures, and I believe that the needle is better adapted for this procedure, especially when operating under local anesthesia. After the tissues have been thoroughly washed with warm sterile saline solution, the testicle is returned to the scrotum. The tunica vaginalis is then approximated and united with a continuous catgut suture. The scrotum is then united with interrupted silkworm sutures. The skin in proximity to the incision is again painted with iodin solution to insure asepsis, a sterile dressing is applied and the scrotum bridged with adhesive tape to give support for the first few days. Eckels also states that, if pus is present, a longitudinal incision should be made in the epididymis and a few strands of silkworm-gut inserted for drainage. In two cases pus formation was found at operation. I have used the procedure described above, and the results obtained were as satisfactory as in those cases in which only inflammation was present.

---

[1] Eckels, Lauren S.: Epididymotomy, THE JOURNAL A. M. A., Aug. 16, 1913, p. 470.

Eckels states that the preparation of the patient is the same as that for a general anesthetic, as local anesthesia is not advisable. I have used it, however, for this operation in several of the cases which I report, with absolute success, hearing no complaints of pain, and noting no symptoms of shock. There may be some pain if an orchitis is present, as happened in one of the cases, but with careful handling of the testicle, this symptom can be obviated. For local anesthesia, a 1 per cent. solution of novocain with epinephrin is infiltrated along the line of the intended incision. Twenty minutes later the incision is made and the tunica is exposed, infiltrated and incised, after which the solution is injected into the epididymis, and anesthesia of the part is complete. The procedure of puncturing and, if necessary, incising, is then absolutely painless. Because of the rapidity with which the operation can be performed, from five to ten minutes being the time required, and the absence of pain and shock, the procedure does not seem to warrant the use of the dangerous general anesthetics.

From a study of the cases at this hospital, the points observed almost entirely agree with the conclusions noted in Eckels' article. The only exception is that I am unable to make any deduction as to the probability that there is a smaller percentage of sterility following the disease in those operated on. I agree with him that the operation should be the procedure of choice in the treatment of epididymitis and believe that the patients should be operated on as soon as symptoms appear, thereby eliminating the possibility of pus and abscess formation.

REPORT OF CASES

Case 1.—J. M., aged 21, a Swede, seaman, applied at the hospital for admission, Aug. 27, 1913. Patient's previous history was unimportant. A few days before admission he noticed a discharge from the urethra. Gonorrhea was diagnosed. Patient was put on the usual treatment and case progressed favorably until September 15, when great pain began in the left testicle. Examination revealed an epididymitis. Operation was performed, September 16, under a general anesthetic. Morning temperature on the day of operation was 38.2 C. (100.76 F.), but became normal at the end of forty-eight hours, with patient comfortable and free from pain. Case progressed favorably and recovery was noted Sept. 23, 1913.

Case 2.—J. G., aged 40, an American seaman, was admitted to the hospital Oct. 11, 1913. Previous history was unimportant. Gonorrhea was diagnosed. Patient was put under treatment and the disease ran the usual course until October 24, when the discharge stopped abruptly. October 30 the right testicle became swollen and the epididymis became enlarged and very painful. Epididymotomy was performed November 1 under general anesthesia. November 2 pain had ceased. November 6 patient was walking around ward and note of recovery was made.

Case 3.—W. H., aged 20, an American seaman, was admitted to the hospital, Sept. 27, 1913. Two weeks previously he noticed a discharge from the urethra and ten days later complained of pain and swelling in the left testicle. Examination revealed gonorrhea complicated by epididymitis. Treatment for the gonorrhea was begun, and palliative measures were employed for the epididymitis. The testicle showed no improvement and on October 8, the patient consented to an operation, which was performed under local anesthesia. Relief from pain was instantaneous, and six days later he was up and about the ward. October 17, patient had fully recovered from the epididymitis. Later however, an endocarditis developed and he was not discharged until Nov. 22, 1913.

Case 4.—J. H., aged 20, a seaman, was admitted to the hospital, Nov. 14, 1913. Eighteen days previously he had noticed a discharge from the urethra. Two days prior to admission he complained of severe pain and swelling in the left testicle. Examination revealed gonorrhea complicated by epididymo-orchitis. Patient was put to bed and given palliative treatment. Temperature on admission was 39.4 C. (102.92 F.). No improvement was noted in his condition and on November 17 the right epididymis became involved. Temperature at that time was 39 C. (102.2 F.). The next day operation was performed on both testicles under local anesthesia. Twenty-four hours after the operation, patient was resting comfortably except for slight pain which was due to the orchitis on the left side. Pain was gone from the right epididymis. At the end of forty-eight hours temperature was normal and all pain absent. November 21, patient was up and about ward. November 25 wound was healed and recovery was noted.

Case 5.—L. A., aged 21, an American seaman, was admitted to the hospital, Nov. 18, 1913. Eight months previously he had first attack of gonorrhea, but had never been cured. The discharge has returned at intervals and lately has been flowing freely. A few days before admission, patient complained of a severe pain in the left testicle. Examination showed a swollen and tender epididymis. He was given palliative treatment until November 23, when he consented to an operation. This was done under local anesthesia. The following day all pain was absent, the swelling reduced and the case made the usual good recovery at the end of six days.

In three other cases operations have been performed under local anesthesia with the same good results, such as absence of pain during operation and the immediate abatement of the symptoms of inflammation.

CONCLUSIONS

Attention is called to the points which are considered most important in favor of the operative procedure.

1. There is immediate abatement of all symptoms for which the patient seeks relief.
2. The tendency to relapse is nil.
3. The operative procedure is without danger as regards anesthesia, because the general anesthetics can be eliminated.
4. This operation as compared with the older methods of treatment is one of utmost importance from an economic point of view, not only to the patient, when loss of time from daily labor is considered, but also to the hospital in its economic administration, by greatly diminishing the number of days of treatment.

I am indebted to Senior Surgeon George W. Stoner, medical officer in charge, for permission to publish this paper, and to P. A. Surgeon W. M. Bryan for his kindness in calling my attention to the article by L. S. Eckels.

Neurasthenia.—The neurasthenic habitually looks at things from the wrong angle. His judgment and ideas, especially those concerning his own condition, are generally hastily drawn, on insufficient grounds, from emotion and suggestion, rather than from reason.—Casamajor.

CONGENITAL PYLORIC STENOSIS

A STUDY OF TWENTY-TWO CASES WITH OPERATION BY THE AUTHOR

H. M. RICHTER, M.D.
Assistant Professor of Surgery, Northwestern University Medical School; Attending Surgeon, Wesley and Cook County Hospitals
CHICAGO

In June, 1911, I placed on record[1] eleven cases of pyloric stenosis in infancy, in which I operated, with one operative death and one death subsequent to operation, which apparently was not due either to the operation or to the original disease. None of the nine infants living at the time of that report has since died, nor has any had a recurrence of symptoms or developed any digestive disturbance of any type. Since then I have operated in eleven cases, with two deaths, making a total of twenty-two cases, with three operative deaths and one death subsequent to recovery from the operation. Though the literature of pyloric stenosis of infancy has become abundant, the study of the cases more and more complete, and simple case-reports exceedingly numerous, it has seemed to me that some phases of my work justify placing it on record.

Of the twenty-two cases, nineteen were of the type described as hypertrophic pyloric stenosis; three were of the type known as spasmodic. In all of the nineteen a definite, firm, olive-shaped tumor was demonstrated at operation; in eighteen of the nineteen it was palpated and recognized through the abdominal wall before the operation. In the only case in which it was not palpable before operation, the clinical findings were so clear that the diagnosis was made without reserve. The tumor consisted of a firm, olive-shaped body, roughly from ½ to ¾ inch in length. It was covered by smooth, glistening peritoneum that had the appearance of being stretched over the mass. There was no external evidence of inflammatory reaction and no attempt at fixation. The mass was as freely movable as a mass at the pylorus so commonly is when found in the adult, and this mobility was recognized clinically and is in fact probably the cause of the frequency with which clinicians have failed to demonstrate it. The tumor had the firmness of cartilage; it was not soft or pliable in any case; there was no case in which its consistency made the finding questionable, no case in which a gradation could be made out between a tumor mass and a mere thickening of the part involved. Moreover, there was no gradation between the tumor mass and the adjacent stomach and duodenum; it was sharply defined. Not in every case is the tumor constantly palpable. It has seemed to me to be more constantly palpable after emptying the stomach by vomiting, or by means of a tube. In two cases in which a pyloroplasty was done, and in one case that came to necropsy, a section of the pylorus showed the mucosa to be relatively redundant, so that it bulged out of the incision when relieved of the compression by the tumor. The histological picture has been perfectly worked out by others; in the one case of my series that came to necropsy the findings agreed with the universal report, namely, a simple hyperplasia of the circular muscle fibers, with no change in any other structure of the pylorus.

The stomach, when it had not been emptied before opening the abdomen by the passage of a tube, was always found distended to a marked degree of tension; the duodenum was always empty and collapsed. It was perfectly evident that the tumor formed a complete obstruction of the canal. In our earlier cases, when we continued the operation without emptying the stomach with an esophageal tube, the various manipulations never forced the air in the stomach through the tumor into the bowel. The bowel remained collapsed and ribbon-like up to the moment of removal of the clamps, when it would balloon out, and the advancing column of air could easily be followed as far as the jejunum was exposed. No hydrostatic test could more clearly prove the existence of a complete block, though the degree of tension was not, of course, determined.

In none of the cases was there any accompanying congenital malformation, though in one (Case 4) a particularly short mesocolon made it impossible to do a retrocolic gastrojejunostomy. Other observers have reported accompanying congenital malformations. A sister of one of the patients (Case 2), the first-born, died of what clinically appeared to be the same condition. In Case 5 a first cousin died of what also was clinically the same condition. Fifteen of the babies were males; all the babies were the firstborn of their parents except one, and in this case the firstborn probably had the same condition. Three of the mothers have since borne children, none of which was abnormal. So far as our records show, there was no parental pathologic condition that could have had any bearing, though our records here are incomplete and probably faulty. In all of our cases the clinical picture was classical. How typical the cases were is evidenced by the fact that in a number of instances in which persons were under observation because of suggestive symptoms, no case was found. Moreover, none of a considerable number of spasmodic cases that were under continuous observation for a satisfactory period, and of which three came to operation, proved to be a hypertrophic case. There were no border-line cases in our series. Moreover, after a very considerable experience with this condition, it is my opinion that the questionable or border-line cases reported in the literature must in some measure at least be dependent on the absence of sufficient clinical material from which to obtain the same broad view of the subject to which we are accustomed in the commoner diseases.

The essential features of the disease have presented a striking uniformity. The onset has always been within a few weeks of birth (usually the second or third); it has usually been abrupt, always with sufficient definiteness to permit the time to be placed within a few days, usually within a day. The first symptom has been spitting up or vomiting, accompanied almost from the start with marked constipation and very soon with a startlingly rapid loss of weight. These symptoms have been uniformly progressive, and the progress has never been arrested for more than a few hours at a time. The symptoms have been unaccompanied by any abdominal distention, rigidity or other feature suggestive of a peritonitis. The lower abdomen has uniformly been found empty and passively retracted, the upper abdomen bulging and tense. Passing across the upper abdomen from under the left costal border toward the right, extraordinarily marked peristaltic waves have always been easily shown. If not present on examination, they could always be induced by giving the babe food or water. They were so marked that they could readily be demonstrated to the audience in a large clinical amphitheater. Finally, as previously stated, in eighteen of the nineteen cases of hypertrophic stenosis, the pyloric tumor could readily be palpated. The existence of the typical condition described does not predicate an absolute closure of the pylorus from the beginning of the symptoms. The tumor mass mechanically blocks the lumen; but it is tunneled by an intact mucous membrane, the closure of which is exactly analogous to the blocking of the urethra by a large prostate. As increasing tension in the urinary bladder may produce an overflow incontinence, so stomach contents may undoubtedly be forced through; and as catheterization may easily be possible with a large catheter, so a relatively large sound may readily be passed through the pylorus. In one case in which I divulsed the pylorus, a case in which the obstruction was complete, I was easily able to pass a fair-sized urethral sound. The tumor here was large and firm, of the typical kind. It is obvious, therefore, that life may be maintained beyond the period at which death might be expected to occur were the closure absolutely impervious. That bismuth may at times be forced

TABLE OF TWENTY-TWO CASES OF CONGENITAL PYLORIC STENOSIS

Case No.	Hospital Record Number	Sex*	Born	Date of Operation	Remarks	Weight			Gain after Operation and Weight at Last Report
						At Birth Pounds	Maximum Pounds	At Operation Pounds	
1	St Marys Hospital†	♂	8/27/08	3/17/09	Vomiting began during first few days and became severe in third week.	8	....	8	45 lbs. at 4 years 10 months
2	Wesley 24,531	♀	4/10/09	5/22/09	Vomiting began in second week and in a few days became excessive.	8½	....	8	39 lbs. at 4 years ½ month.
3	Wesley 24,717 24,931	♂	3/ 3/09	6/10/09	Well for five weeks—began to vomit during sixth week.	......	....	8 3/16	Died one month after operation of a gastro-intestinal disturbance.
4	St. Luke's 56,252	♂	6/25/10	7/20/10	Began 3rd or 4th day and became excessive at the end of two weeks.	7 3/16	7 11/16	6½	39½ lbs. at 3 years 4 months.
5	St. Luke's 56,511	♀	7/ 5/10	8/ 4/10	Vomited once each on 10th, 14th and 18th days, and "everything" from 23rd day on.	8	8½	6⅞	38 lbs. at 3 years 3 months.
6	St. Luke's 58,914	♀	9/24/10	12/24/10	"Spitting up" from first few days; vomiting became excessive in 6th week.	9	10	7¾	9 lbs. 12 oz. 28 days after operation; 35 lbs. at 37 mos.
7	Wesley 30,698	♂	11/19/10	1/27/11	Began to vomit in 3rd week, and by 5th week was vomiting everything.	10	....	7	33 lbs. at 2 years 11 months.
8	Wesley 31,564	♂	2/14/11	4/ 4/11	Began "spitting up" during first few days, and vomited everything after 14th day.	10¾	11 3/16	8	37½ lbs. at 32 months.
9	Wesley 31,712	♂	3/14/11	4/13/11	Vomiting began during first few days and early became marked	8	8½	5¾	Died.
10	Wesley 31,970	♂	12/16/10	4/28/11	Vomiting began immediately after birth and became excessive during first week.	5¼	6 13/16	‡	After losing 4 oz., gained 21 oz. in 20 days; 30 lbs. at 30 months; 33 lbs. at 35 months.
11	Wesley 31,993	♂	3/17/11	5/ 4/11	Began during 4th week and vomited "everything" after 35th day.	7	7¾	5 13/16	26 lbs. at 2 years.
12	St. Luke's 65,219	♀	11/ 1/11	12/16/11	Began with spitting up on the 7th day; vomiting soon became excessive and expulsive; stools mostly greenish mucous.	10½	§	7½	26 oz. in first 53 days; 29½ lbs. at 23½ months.
13	Wesley 36,194	♂	2/ 6/12	3/16/12	Onset at 3 weeks.	8½	9	7	64 oz. in first 65 days; 25 lbs at 14 months.
14	Wesley 37,316	♂	4/ 9/12	6/ 9/12	Vomiting began in 3rd and 4th weeks. Progressively worse up to time of operation.	......	....	5⅞	Evisceration following removal of sutures on 4th day; child never reacted from shock, and died soon after leaving the hospital.
15	St. Luke's 68,743	♀	5/19/12	6/22/12	Vomiting began first week after birth, gradually increased and became profuse and expulsive	8¼	9	7½	6½ lbs. in 4½ months, 23 lbs. at 16 months.
16	Wesley 37,629	♂	5/25/12	6/30/12	Obstruction complete for 5 days preceding operation. No bowel movement.	8½	....	7 1/16	29 lbs. at 17 months.
17	Wesley 38,454	♂	6/15/12	9/ 3/12	Symptoms developed gradually in 2nd and 3rd week; gained weight slowly for 6 weeks; then lost; under observation 10 days before operation. Held its own for 5 days, then lost very rapidly, vomiting blood last 24 hours.	8	....	6¾	Gained rapidly from start. 21 lbs. at 8½ months.
18	Wesley 40,185	♂	12/10/12	1/ 8/13	Onset in 2nd week.	......	....	7 7/16	Died.
19	Wesley 40,343	♂	12/25/12	1/17/13	Vomiting began suddenly on 15th day, "as though pumped up;" apparently more than child took in. Thick yellow, never dark or green. Stools only a little black jelly.	9	‖	6 11/16	11 oz. in first 18 days; 18½ lbs. at 8 months.
20	Wesley 40,707	♂	12/10/12	2/12/13	Vomiting began at 4 weeks; in 2 weeks lost 28 oz.; in next 2 weeks, 23 oz. Vomited more than he took in.	7¾	9½	6 5/16	60 oz. in first 55 days; 21 lbs. 9 oz. at 10 months.
21	St. Luke's 78,171	♂	7/27/13	10/30/13	Vomiting began very suddenly in 5th week; excessive from the beginning.	7½	9	8½	Recent; gaining rapidly.
22	St. Luke's 79,165	♀	10/25/13	12/ 4/13	Began vomiting 10 days after birth; became excessive with great suddenness on 30th day.	7 14/16	8	6 11/16	Gaining rapidly.

*In this column ♂ stands for male and ♀ for female. †Green Bay, Wis. ‡Lost 4 ounces during next few days. §No increase. ‖Gained—no record of amount.

Summary: Operative Mortality, three in twenty-two cases; one death subsequent to operation. No recurrence of symptoms, and no postoperative sequelae in cases ranging up to 5 years of age. Without exception, the weight of the children subsequent to operation has been normal, or above the average weight of children of their age. Operation used: Case 16, divulsion of the pylorus; Cases 17 and 18, submucous pyloroplasty. The remaining cases were typical posterior gastrojejunostomies.

through, or that a suggestion of a milk stool occur, must therefore not rule out the diagnosis.

It is particularly important that the Roentgen ray, as a diagnostic measure, be limited to determining the rate of emptying the stomach, not the patency of the pylorus. To exclude a diagnosis of hypertrophic stenosis on the basis of the passage of bismuth is sure to lead to serious error. I am personally aware of two cases in which this error was made, and operation advised against. In both cases the diagnosis was later confirmed; in one by necropsy, in the other at the delayed operation, which failed to save the baby.

Carrying further the analogy to the mechanical conditions present in prostatic enlargement, it may be conceded that sufficient patency may persist to maintain life even after temporary total blocking has been evident. Only on this basis can we account for the recoveries that have been reported by competent observers. The recovery does not imply the disappearance of the tumor. When advocates of non-operative treatment admit that obstructive symptoms persist for years after the immediate dangerous symptoms subside, they tacitly admit the persistence of the cause of the obstruction. Heubner describes symptoms persisting into the third, fourth and seventh years of life. Recently much collateral evidence has pointed in the same direction. Wolbach performed a necropsy on a child 8 months of age that had been operated on at the age of 1 month for hypertrophic pyloric stenosis. The child was symptomatically cured during the intervening seven months, and the death was in no way associated with the original condition. The tumor found at the necropsy was apparently as large as at the time of operation. In an address before the Illinois State Medical Society, in May, 1913, Scudder showed roentgenograms of cases in which operation had been performed at varying periods previously in which he demonstrated that bismuth failed to pass through the pylorus, but passed by way of the new opening into the jejunum. It was evident that the pylorus had remained impassable. To any one familiar with the tendency of stomach contents to ignore the new opening and pass by way of the pylorus, when it possibly can, such roentgenograms are conclusive.

There is nothing, however, in the nature of hypertrophic stenosis that essentially predicates a permanent pyloric closure. I am not aware that any good reason has been given why these tumors should not ultimately disappear. They are not neoplasms, but simple muscular hypertrophies. The indication for operation is not strengthened by proving the permanency of the mass. The fact that it does not disappear quickly enough is the essential, absolute indication for surgical interference. Dr. James T. Case of Battle Creek, Mich., is now making Roentgen studies of my cases of varying ages, nine of which have been completed, and will shortly publish them. They will, I believe, confirm to a great extent Scudder's findings.[2]

Congenital hypertrophic stenosis of the pylorus presents, then, the following condition:

A mechanical intestinal obstruction of a high grade, or possibly complete, the mechanism of which is such that life may be prolonged for weeks, but that usually results fatally in from six to ten weeks. In a certain proportion of the cases in which recovery occurs, evidence of incomplete obstruction persists for months or years. In the spasmodic type of pyloric obstruction, complete recovery usually follows persistent treatment, but the condition at times resists treatment for so long a time as materially to endanger the child's life by interfering with its nutrition.

It is impossible to reconcile the conflicting ideas that prevail as to the death-rate of hypertrophic stenosis under non-surgical treatment. No large series has been treated non-surgically in America. The German statistics give the mortality as close to 20 per cent. Nearly all the British writers rate it high; but Hutchison, in 1910, reported a remarkable series of cases treated non-surgically, with results entirely different from all other observers, and hard to understand. In a series of seventeen cases in private practice there was no death; in sixty-four cases treated in hospital practice the death-rate was 78 per cent. I am unable to analyze his results and merely give them as they are published. The surgical statistics have given so high a death-rate that operative interference has often been declined in the past, even when the prognosis was otherwise admittedly bad. Up to five years ago the operative mortality was easily 50 per cent. of the cases reported, and in the unreported cases it was notoriously higher. Since then the increasing number of cases recognized in the earlier stages has given surgeons an opportunity to interfere before the child reaches a moribund state. The result is that a number of operators have been able to develop their technic to the point of securing results that serve at least to show that the condition is not inoperable.

In presenting this series of twenty-two cases, which is the largest heretofore published in America, I wish to bring out the facts, first, that the mortality has been reduced below that claimed by any method of non-surgical treatment, and, secondly, and of equal importance, that the ultimate condition of the patient is that of a normal person.

My mortality, as stated above, was 13.6 per cent. Of the twenty-two operations, nineteen were typical posterior gastro-enterostomies, with two deaths, a mortality of 10.5 per cent. On two babies I did a submucous pyloroplasty, and on one a divulsion of the pylorus. Of the three deaths that occurred, one was essentially a result of the child's condition, and represents an irreducible mortality that must prevail so long as patients are not early regarded as surgical cases. Two of the deaths were clearly attributable to faulty technic. In one an unsuccessful modified pyloroplasty necessitated an immediate gastro-enterostomy. The child was unable to stand the shock of the double operation. In the other case, through a misunderstanding, the sutures were removed on the fourth day; the wound opened up, and in the absence of one of the older members of the house staff the child was allowed to eviscerate itself. Neither death should have occurred. They represent the cost of developing new methods.

The second consideration in the question of operative interference is the immediate and ultimate condition of the child.

Of the nineteen patients who survived operation, one died of what was diagnosed as an acute food intoxication. The child lived in the crowded district immediately adjacent to the dispensary. During the hottest period of the summer, in August, it was brought back to the hospital less than a month after operation, with vomiting and diarrhea, and died after an illness of six days. A post-mortem was not permitted. Two of the seventeen cases had postoperative sequelae, necessitating reopening the abdomen.

---

[2] I wish to acknowledge my great indebtedness to the management of St. Luke's Hospital for the free use of their Roentgen ray room and other accommodations for the purpose of this study.

My first patient developed an acute intestinal obstruction eight weeks after the primary operation. When the abdomen was opened, extensive adhesions were found, the nature of which I discussed in a former paper. The child recovered.

In Case 7 the patient[3] developed a volvulus of the entire small bowel, which was relieved by laparotomy.

These complications occurred in Cases 4, 1 and 7, respectively, and were reported in my first paper; no postoperative sequelae of any kind have developed in my last fourteen cases. The first patient was operated on five years ago, the others at intervals since. None has shown any postoperative sequel in the form of hernia, recurring obstruction or any other evidence of mechanical harm from the operation.

All of the eighteen living patients are now under observation, or have been up to within the past few weeks. After the first few days, during which there was usually a loss of several ounces, the gain in weight was pronounced and continuous. There was no exception to this rule. Probably because they were closely watched, fifteen of these babies, at ages varying from 8 months to 4 years and 10 months, weighed more than the normal average of children of their age, as given in the usual tables in use by pediatricians; one, Case 11, is practically normal, weighing 26 pounds at 24 months; and two are too recently operated on to determine the ultimate effect, but are gaining at the rate of 1 to 2 ounces per day.

There was usually some vomiting during the first week following operation. In nearly all cases vomiting ceased before the patient left the hospital, and without exception vomiting has not recurred in any case to date. There have been no intestinal disturbances in any case suggestive of a disturbed digestion. No chemical studies of the stools have been made in my cases, but a sufficient number of such studies have been made to justify a positive statement to the effect that no change in digestion capable of demonstration is made.

PAROXYSMAL HEMOGLOBINURIA

WITH REPORT OF A CASE

W. W. YOUNG, M.D.

BOSTON

History.—J., a man aged 45, Swedish, a sheet-metal worker, entered the Peter Bent Brigham Hospital, Sept. 11, 1913, complaining of chills, fever and bloody urine. The family history was unimportant as related to the present illness. The patient had interstitial keratitis at 3 years (?), and measles and small-pox as a child, but no other infectious diseases in childhood. The patient came to the United States nineteen years ago and served in the Navy during the Spanish-American War. He has been a sailor for several years since, usually serving as engineer on a private yacht. Patient has not been south of New York for twelve years. Ten years ago he had an attack of pneumonia; there was no residue. Four years ago in September, patient had a sudden chill, followed in one hour by fever and sweating. Following this attack, he passed dark urine for from six to eight hours. The next day he felt perfectly well. He had no more attacks that year. During the following fall and winter there were five or six attacks of a similar nature, and two years ago and last year patient had four or five attacks similar in every respect to those previously experienced. These attacks always followed some slight exposure to dampness or cold. He would have a chilly sensation, his legs would become numb and cold, and then a shaking chill would follow. These chills varied in intensity. With each attack he passed dark urine. In the spring of 1913 he experienced another attack. Quinin has been taken in large doses but produces no effect. Patient denies lues. His habits were unimportant.

Present Illness.—September 10, at 9 a. m., patient was standing on the street and felt chilly. At 10 a. m. an attack similar in all respects to the preceding started with a chill, followed by fever and sweating at 11 a. m. with the passing of dark urine.

Physical Examination.—This shows a well-built white man, lying quietly in bed. The pupils of the eyes are irregular, being the shape of apple-seed. The lower iris appears to be drawn into a scar. The corneas are cloudy. The teeth are in good condition. The throat is negative. There is no general enlargement of the lymph-nodes. The chest and lungs are negative. Both heart-sounds are heard and normal; there are no murmurs. The pulse is of good quality, regular and normal. The systolic blood-pressure is 118, diastolic 68. The abdomen is negative; spleen is not palpable; liver shows no enlargement; there are no masses and no tenderness. The extremities show no scars or edema. The deep and superficial reflexes are elicited and found normal.

Clinical Findings.—Blood: Hemoglobin (Sahli); 90 per cent.; white blood-cells, 8,600; no malarial parasites; differential count, normal; platelets, 400,000 per cubic millimeter. The stool contains no blood or parasitic ova, and is essentially negative. The urine is amber, clear and shows no albumin, blood or casts. The Wassermann reaction (blood-serum) is positive.

Course.—September 15: Patient had an attack of chills followed by fever and sweating. No malarial parasites are found. Urine is port wine color and contains much albumin and many pigment casts, but no blood. Spectroscope shows bands of oxyhemoglobin.

September 16: Patient's feet were soaked in ice-water for twenty minutes. One hour later hemoglobin was demonstrated in the urine. There was no chill or fever.

September 17: Neosalvarsan, 0.6 gm., was administered intravenously.

September 18: Wassermann reaction (blood-serum) was positive.

September 23: Patient had one of his attacks at 9 a. m.

September 24: Neosalvarsan, 0.6 gm., was administered intravenously.

September 25: Wassermann (blood-serum) was positive.

September 28: Patient had another attack, much less severe. There was no chill and no fever.

September 29: The feet were soaked in ice-water twenty minutes. Urine exhibited hemoglobin. Patient was discharged to return at intervals for treatment.

October 2: Salvarsan, 0.4 gm., was administered intravenously.

October 16: Salvarsan, 0.4 gm., was administered intravenously.

October 24: Patient reported a paroxysm, less severe than former ones.

November 12: Salvarsan, 0.4 gm., was administered intravenously.

The patient is now on intramuscular injections of salicylate of mercury.

TEST FOR PATHOLOGIC FRAGILITY

* Hemolysis.
† Partial hemolysis.

Additional Data.—Just after the onset of an attack the patient's blood was drawn from the median basilic vein. On centrifugalizing the serum was deeply tinged with red and showed the characteristic bands of oxyhemoglobin with the spectroscope, thus demonstrating an actual hemoglobinemia.

---

[3] By an error referred to as Case 8 in my original paper.

During an attack the patient's blood was drawn into citrate-salt solution to prevent clotting. The corpuscles were then centrifuged and washed. These were suspended in various strengths of salt solution paralleled by control in order to determine the presence of pathologic fragility; with the result which is tabulated.

The conclusion was drawn that there probably existed no very definite pathologic fragility in the cellular elements of the blood.

Donath and Landsteiner,[1] in 1906, studied a case of paroxysmal hemoglobinuria and found that they could reproduce *in vitro* what had occurred *in vivo.* They found that they could hemolyze the patient's corpuscles with the patient's serum when the two in contact were cooled to 0 C. (32 F.) for half an hour and subsequently incubated at 37 C. (98.6 F.) for three hours. Cooke,[2] in a series of exhaustive experiments, found the same true of his patient. He modified the original Landsteiner technic as follows: Instead of the subsequent incubation for three hours, he found that by careful heating over a burner he could obtain hemolysis with subsequent incubation for half an hour. The blood of the patient, J., was taken from the median vein and caught in citrate-salt solution (1 part of solution to 4 of blood) and treated as follows:

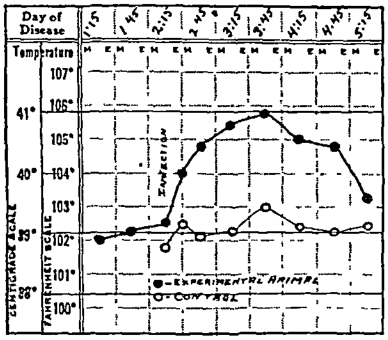

Chart 1.—Temperature curves of rabbit injected with oxyhemoglobin and of control rabbit injected with salt solution.

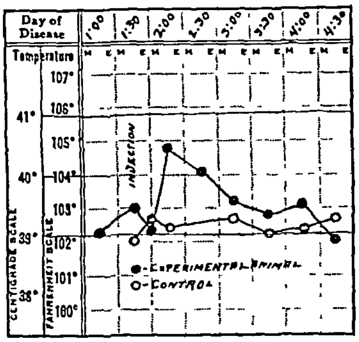

Chart 2.—Temperature curves of rabbit injected with oxyhemoglobin and control receiving no injection.

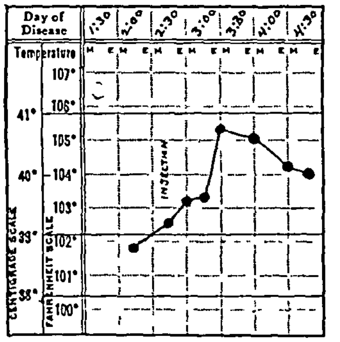

Chart 3.—Temperature curve of rabbit injected with oxyhemoglobin. No control.

PATIENT'S BLOOD

Cooled to 0 C. for half an hour. No hemolysis.

Heated and incubated at 37 C. for half an hour. No hemolysis.

Cooled to 0 C. for half an hour and heated and incubated at 37 C. for half an hour. Hemolysis almost complete (whole blood).

Patient's washed corpuscles (suspended in normal salt solution) cooled to 0 C. for half an hour and heated and incubated at 37 C. for half an hour. No hemolysis.

CONTROL BLOOD

Cooled to 0 C. for half an hour. No hemolysis.

Heated and incubated at 37 C. for half an hour. No hemolysis.

Cooled to 0 C. for half an hour and heated and incubated at 37 C. for half an hour. No hemolysis.

We also found, as others before had found, that the patient's serum would hemolyze the corpuscles from another person, while the serum of the other person would not hemolyze the patient's corpuscles.

PATIENT'S SERUM AGAINST CONTROL'S WASHED CORPUSCLES

Washed corpuscles, cooled to 0 C. for half an hour and heated and incubated at 37 C. for half an hour. Hemolysis complete.

CONTROL'S SERUM AGAINST PATIENT'S WASHED CORPUSCLES

Washed corpuscles cooled to 0 C. for half an hour and heated and incubated at 37 C. for half an hour. No hemolysis.

No attempt was made to do this quantitatively but merely to establish this case as a clinical entity by using the reaction diagnostically.

The occurrence of paroxysms of hemoglobinuria, the absence of malarial organisms, the increase in blood platelets, the hemoglobinuria after cooling the extremities, and finally the demonstration in the blood of an autohemolysin without increased corpuscular fragility seem to warrant the diagnosis of paroxysmal hemoglobinuria, so-called.

As to the nature of the autohemolysin, Cooke,[2] in his most admirable work, established the following in his case: 1. An autohemolysin exists. 2. The reaction follows the Ehrlich theory of complement—antibody-cell combination. 3. The mode of action is as follows: The antibody may be taken up from inactive serum (patient's) in the cold, the combination with the corpuscles being rather unstable; complement is absorbed from active serum together with antibody in the cold; complement unites with antibody only under the influence of cold; red blood-cells exposed to inactive serum are more or less resistant to hemolysis on account of complementoid present. He concludes that antibody unites with corpuscle and complement with antibody only under the influence of cold, the lytic action being exhibited on subsequent elevation of temperature.

SYMPTOMATOLOGY

The paroxysms exhibited by our patient resemble in almost every respect those seen in malarial infections. Browne,[3] in experiments on rabbits, was able to produce paroxysms resembling those seen in malarial infection by injections of hematin intravenously. Inasmuch as the paroxysms of the hemoglobinuric so closely resemble malaria, it was thought that perhaps here, too, the phenomena were due to the releasing of blood pigment into the menstruum. To test this theory, several rabbits were injected intravenously with hemoglobin. Enough rabbit's blood was drawn to give about 1.5 c.c. of corpuscles. The blood was defibrinated, centrifuged, and the corpuscles laked with sterile distilled water and made up with sterile salt solution. This was controlled.

by examination with the spectroscope, and was used for injection. The controls received injections of normal salt solution. No attempt at dosage was made, but this amount was taken arbitrarily.

The reaction produced was as follows: The animal when first injected was restless, soon becoming droopy, crouching in a corner with its ears back and hair erect. The vessels of the ears were constricted and the ears cold. This lasted for from fifteen minutes to half an hour and was followed by a period when the peripheral vessels were dilated and the ears warm. The temperature began to rise immediately after injection and reached a maximum in from half an hour to one hour, the elevation lasting for irregular periods. This is shown in the accompanying charts. Some animals reacted better than others. In no instance, even on increasing the dosage greatly, could anything simulating the shaking chill be produced. It seems suggestive, though not conclusive, that the loosing of hemoglobin into the blood-stream produces the reaction seen in hemoglobinurics and not the factor, whatever it may be, which causes the hemolysis. The fate of the hemoglobin after injection cannot be determined. It may perhaps undergo some change in the body before producing the reaction.

ETIOLOGY

Cooke[2] states that, since the introduction of the Wassermann reaction, 90 per cent. of hemoglobinurics give a positive reaction. Previous to that time a history or stigmata of lues could be obtained in many instances. Barrett and Yorke[4] state that they could find in the blood of persons infected with the organism of malarial fever no such autohemolysin as has been demonstrated in the serum of the hemoglobinuric. Landsteiner[1] found in six out of sixty-five cases of general paresis that the blood of the individual contained an autohemolysin giving the reaction seen in hemoglobinurics. Several patients with syphilitic involvement of the central nervous system, including tabes and cerebrospinal syphilis, were examined here and some found to possess in their blood-serum an autohemolysin. When such a person had his feet soaked in ice-water for twenty minutes, no hemoglobinuria resulted. This suggested the possibility that the hemoglobinuric might possess a kidney with an increased permeability; witness the albumin and casts at the time of a paroxysm. To determine this point, the various renal function tests were tried.

In the case of J., phenolsulphonephthalein (1 c.c. standard solution given intramuscularly) resulted in an excretion of 55 per cent. the first hour, and a total excretion the second hour of 80 per cent.

The total amount of potassium iodid, 10 gm., was excreted in forty-eight hours.

The sodium chlorid output on the "house diet" (from 7 to 9 gm. of sodium chlorid) was 7.4 gm.; plus 10 gm. of sodium chlorid, it was 16.4 gm. the first day, 14.7 gm. the second day, and 10.6 gm. the third day.

The total nitrogen output on the "house diet" was 15.9 gm.; plus 20 gm. of urea it was 26.8 gm. the first day and 18.5 gm. the second day.

The phenolsulphonephthalein and potassium iodid were certainly put out in excess of normal, whereas the salt and nitrogen were at the upper limit of normal. It is suggestive, though we can draw no definite conclusions from one case, of a certain degree of hyperpermeability.

On the whole, a luetic rather than a malarial origin seems the more plausible in view of our present knowledge.

TREATMENT

Pringsheim,[5] by the intramuscular injection of cholesterin emulsions was able to hold the paroxysms in abeyance in one patient. Unfortunately, he lost sight of his patient and could not follow up his admirable start. In the case of J., addition of cholesterin to the serum *in vitro* inhibited the hemolysin exhibited by the control without cholesterin, owing probably to its anticomplementary properties. A vigorous antisyphilitic regimen seems the much more plausible course in view of the positive Wassermann. This was undertaken in the case of J. No case heretofore has been followed up to the point at which the Wassermann has become negative. At present, the Wassermann in this case is positive, though titration shows it to be weaker than at the first examination. The paroxysms have grown progressively less frequent and less severe. The case, however, will have to be followed up to the point of the Wassermann's becoming negative.

SUMMARY

We have before us a patient in whose blood-serum, either constantly to act on exposure to cold or else brought into existence by cold, exists a substance which hemolyzes the red blood-cells. This gives rise to a hemoglobinemia which in turn provokes the phenomena of a paroxysm very much like that provoked by the loosing of hematin by the action of the malarial parasite. The excretion of the hemoglobin in the urine by the kidneys is one of the most striking of the phenomena and gives the disease its name. This autohemolytic substance in the blood is in all probability the result of infection by the *Spirochaeta pallida*. On the other hand, the possibility exists that the same substance which is produced by the organism of syphilis and to which we give the name antibody and which produces fixation of complement, thus giving a positive Wassermann, is produced by some other agency in the disease under discussion. Thus there may exist a positive Wassermann without syphilis. The existence of this same substance, which gives rise to hemolysis, in parasyphilitics, so-called, makes it highly probable that the etiologic factor here, too, is syphilis. It is quite possible that hemolysis may take place in the menstruum of the parasyphilitic and that it is an increased permeability in the hemoglobinuric which gives rise to actual hemoglobinuria.

It remains to be seen whether or not specific treatment will help clear up the difficulty of etiology, and this I shall report later.

697 Huntington Avenue.

Early Questions.—Another unfortunate tendency among the Arabs was their liking for the discussion of many trivial questions. Hyrtl, in his volume on Arabian and Hebrew Words in Anatomy," declares that it is almost incredible how earnestly some trivial questions in anatomy and physiology were discussed by the Arabs. He gives some examples. Why does no hair grow on the nose of men? Why does the stomach not lie behind the mouth? Why does the wind-pipe not lie behind the esophagus? Why are the breasts not on the abdomen? Why are not the calves on the anterior portion of the legs? Even such men as Rhazes and Avicenna discussed such questions.—Walsh, Makers of Medicine.

CORPUS LUTEUM ORGANOTHERAPY IN CLINICAL PRACTICE

WITH REPORT OF A CASE OF BILATERAL SALPINGO-OOPHORECTOMY IN WHICH THE ADMINISTRATION OF CORPUS LUTEUM EXTRACT WAS FOLLOWED BY THE REESTABLISHMENT OF MENSTRUATION

WALTER T. DANNREUTHER, M.D.
Surgeon to St. Elizabeth's Hospital and St. Bartholomew's Clinic
NEW YORK

Recent experimental and clinical investigations have determined and established the following important facts:

1. The human ovary has an internal secretion.
2. *This internal secretion dominates menstruation* and maintains pregnancy during the early months.
3. Corpus luteum is the structure chiefly concerned and the probable source of the internal secretion.
4. The corpus luteum of pregnancy is more stable than that of ovulation.
5. Corpus luteum has a selective action on the endometrium and prepares the uterine mucosa for the reception of the ovum.
6. The acme of development of corpus luteum is synchronous with the onset of menstruation.
7. There is a distinct relationship between corpus luteum and the other internal secretory structures of the body.
8. Removal of all lutean tissue is followed by cessation of the menstrual flow.
9. Animal corpus luteum, when administered by the mouth in average doses, is non-toxic.

For many years, the elaboration of an internal secretion by the human ovary was a much-mooted and disputed question, and it was not until after the publication of Fraenkel's masterly paper in 1903 that this theory was accepted as a physiologic truth. Fraenkel's experiments and deductions were later substantiated by other investigators, interest in the possibilities of ovarian and corpus luteum organotherapy being greatly stimulated in consequence. That the latter is of immense practical value, several clinical workers have now demonstrated beyond all question.

OVARIAN EXTRACTS UNSATISFACTORY

With the introduction to the profession of other organic extracts as therapeutic adjuncts in the treatment of disease, animal ovarian extracts were for a time extensively employed for a variety of gynecologic ailments. Unfortunately, however, in the experience of many, including myself, the use of these ovarian preparations proved a partial or complete failure in so many instances that their popularity soon waned. Their clinical inefficiency was indeed disappointing. The chief faults empiricism manifested were (1) in disregard of the fact that corpus luteum is the structure from which the internal secretion of the ovary is derived, as suggested by its histologic structure (large epithelial cells with pale staining nuclei, lying in close approximation with numerous small, thin-walled blood-vessels, characteristic of *the organs of internal secretion*); (2) in failure to exercise proper discrimination in the selection of cases (the best results are to be expected in those conditions which are due to deficient and not to excessive ovarian activity); and (3) in administration of doses (of the ovarian preparations) that were entirely inadequate. In other words, a corpus luteum rather than an ovarian extract should be used, cases must be carefully selected, and the dose should be regulated according to the individual patient and the toleration of her circulatory apparatus.

INDICATIONS FOR THE USE OF CORPUS LUTEUM EXTRACT

Those who have employed corpus luteum (the fresh yellow body) or a desiccated extract of it, using proper discretion, have found that it is much more potent than the ovarian preparations and that its administration in suitable cases is followed by striking and gratifying results. The particular conditions for which it will be found serviceable and to which its use should be limited are: (1) functional amenorrhea or scanty menstruation; (2) dysmenorrhea of ovarian origin; (3) manifestations of physiologic or artificial menopause, such as nervous or congestive disturbances of reflex origin (hot flashes, psychoneuroses, etc.); (4) "neurasthenic" symptoms during menstrual life; (5) sterility, not due to pyogenic infections or mechanical obstruction; (6) where the function of one ovary is impaired, or one ovary has been removed, and the compensatory activity of the other is insufficient; (7) repeated abortions, not due to disease or mechanical factors, and (8) hyperemesis in the early months of pregnancy.

It seems almost superfluous to mention that it would be useless to prescribe corpus luteum in cases such as amenorrhea due to extreme anemia, dysmenorrhea due to cervical stenosis, or all cases of sterility, but it is a fact that otherwise discerning practitioners have prescribed it for diverse gynecologic conditions with an equal disregard of its indications and without exercising their good judgment. Therefore, additional emphasis on the necessity for the proper selection of cases is essential in order that this useful preparation may not be unjustly discredited.

CLINICAL OBSERVATIONS

In a paper presented before the Section on Obstetrics and Gynecology of the American Medical Association, Burnam,[1] gives a comprehensive review of previous literature, and a detailed account of clinical experiences, in conjunction with Kelly, with corpus luteum. They were among the first in this country to employ it extensively in actual practice. In large part, my own experience with corpus luteum therapy corroborates Burnam's observations, but there are several additional phenomena, which he failed to mention, that I have noted and that seem to be of major importance. I agree with him that (1) animal corpus luteum, either fresh or as an extract, when administered by mouth in average doses, is non-toxic; (2) slight gastric disturbance occurs occasionally, but soon disappears; (3) this agent decreases blood-pressure; (4) a desiccated extract is more satisfactory and convenient than the fresh yellow body, and (5) it should be used in comparatively large doses. In addition to the foregoing, I have observed that (1) at first, patients taking corpus luteum often complain of vertigo, but this rapidly disappears; (2) toleration is soon established; (3) *its physiologic action does not resemble that of* adrenalin and it does not elevate blood-pressure, as some writers have asserted (Wilmer Krusen and others); (4) the pulse-rate is usually increased; (5) it is of the utmost importance to employ an extract obtained from the ovaries of pregnant animals only, and (6) constant supervision of the blood-pressure of patients taking corpus luteum is imperative.

---

IMPORTANCE OF USING AN EXTRACT OBTAINED FROM THE OVARIES OF PREGNANT ANIMALS ONLY

Many of the large pharmaceutical manufacturers are now marketing preparations of corpus luteum, but these vary to such an extent regarding their source, method of preparation and nomenclature that another element of confusion is created. A distinction should be made between corpus luteum (the fresh yellow body), ordinary desiccated extracts and those made from the ovaries of pregnant animals exclusively. The use of fresh corpus luteum, which was formerly fed to patients as a salad or sandwich in large and uncertain doses, has now been discontinued, principally because the fresh glandular substance is very delicate, easily affected by atmospheric conditions and chemicals, and the dosage is not always identical.

Many firms are producing a desiccated extract, naming their preparations appropriately but not uniformly. They are known as lutein, corpus luteum extract, extract corpora lutea, etc., and are all obtained from the ovaries of cows or sows. On personal inquiry, only one of the larger firms would give a positive assurance that the animals from which the extract was derived were pregnant ones only. I have used, to the practical exclusion of all others, an extract obtained from pregnant cows, and although it cannot be accurately assayed, this preparation represents approximately six times the weight of the moist glandular substance: 5 grains of the extract is equivalent to 30 grains of the fresh yellow body.

One firm markets its preparation in the form of compressed tablets of 20 grains each, while others dispense theirs to the druggists in cartons. The dose of most of these products is said to be 20 to 120 grains three times daily, the manufacturers asserting that such quantities may be taken with safety. But when the extract is derived from pregnant animals such dosage is excessive. One factor of importance in the lack of uniformity in the clinical results of many observers is probably a non-appreciation of the relative variations in activity in different corpus luteum preparations, depending on whether they are made from the ovaries of pregnant animals or from all ovaries indiscriminately. A properly made extract will often prove of material benefit in a case in which large doses of an ordinary extract have failed to relieve.

DOSAGE

I prescribe 5-grain capsules three times a day and have seldom had occasion to increase this quantity, although 10-grain doses have been necessary in certain instances. The potency of such amounts is almost a verification of the source of the extract. Under no circumstances would I prescribe the dosage that Burnam recommends, if it were certain that all extracts were made from the ovaries of pregnant animals. I have nearly always observed a reduction of blood-pressure after a week's use of the 5-grain doses, and whenever the pressure drops too rapidly the patient is ordered to discontinue its use temporarily. Before the physician gives a patient corpus luteum he should take a careful sphygmomanometric reading, and weekly readings thereafter. If the blood-pressure falls as much as 15 mm. the therapy should be stopped until 10 mm. of this loss has been recovered, when it may be cautiously resumed. At times, however, a decrease of even 15 mm. of blood-pressure would be beyond the limit of safety, as it should never be permitted to fall below 90 mm. Hg under any circumstances. If these principles are accepted as a guide, corpus luteum organotherapy will not be followed by any untoward effects on the patient's circulatory apparatus. Another point of importance is the necessity for always getting a comparatively freshly made extract. I would place the limit of time on its reliability after manufacture at about three months.

PERSONAL EXPERIENCES

The cost of corpus luteum extract somewhat precludes its utilization in dispensary practice, so that the opportunities for its employment are to a certain extent restricted. My personal experience includes about eighty carefully selected cases, the greater number of which were encountered in private practice, and with few exceptions the results have been very encouraging.

All are familiar with the slightly obese, pale and anemic type of young woman, who soon after puberty consults the physician because of headaches, malaise, nervousness, acne vulgaris, constipation and scanty menstruation. While proper hygienic measures, arsenic and iron are of course of value, the conjoint administration of corpus luteum extract apparently promotes the menstrual flow and has a salutary effect on the general economy. In addition, I have frequently noted a loss of the excess in weight and a marked improvement in tissue tonicity in these patients.

Cases of dysmenorrhea due to functional ovarian deficiency have almost invariably been relieved by corpus luteum. I have seen a number of women suffering from this condition who had previously taken an ordinary corpus luteum extract without benefit, but who were subsequently relieved by an extract made from the ovaries of pregnant animals.

Climacteric symptoms, such as hot flashes, psychoses. vesical irritation, etc., due either to the physiologic or artificial menopause, may be prevented or readily controlled. In fact, the results in these cases are most striking of all. The efficiency of corpus luteum in such conditions has been demonstrated repeatedly, and it is a source of great satisfaction to both patient and physician to have these distressing symptoms promptly relieved, particularly after hydrotherapy, the valerianates, bromids, etc., have proved of no advantage. I would urge its administration as a routine measure in all cases approaching the menopause, and after hysterectomy and oophorectomy, partial or complete. In two cases of pruritus vulvae, associated with the menopause, the itching was so quickly alleviated by corpus luteum that it would almost indicate a selective action on the external genitalia.

Patients complaining of headaches, neuromuscular weakness, mental irritability, insomnia and other variable and inconstant subjective symptoms, and in whom no pathologic cause can be determined, are frequently seen. Such instances of so-called "neurasthenia" occurring in women during menstrual life are but vague entities, to say the least, and are often really reflex manifestations of menstrual disturbances. It has recently been my privilege to observe an instructive case in this connection. The patient was a young woman, aged 25, in excellent general health. She had had one miscarriage four years before I saw her, bore one child a year later and had another miscarriage about a year after the child's birth. After both miscarriages she was curetted, and since the last curettage menstruation was scanty and body weight increased, and she became nervous, morose and irritable. Pelvic examination revealed nothing abnormal to me at this time, notwithstanding which she was subjected to laparotomy for prolapsed ovary (?) by her physician. After this, her condition become somewhat improved for a short time, probably due to the psychic effect of the operation, but she soon lapsed into her former state. Two other gynecologists were then consulted, both of whom suggested "corpus luteum." The preparations prescribed failed to help her and her condition remained about the same until a short time ago, when she consulted me and the use of an extract made from pregnant animals' ovaries was advised. From that time on, she began to improve and all her unpleasant symptoms gradually cleared up. In short, this patient was a healthy, well-nourished young woman, in possession of normal pelvic organs, whose symptoms, attributable only to menstrual disturbance, were entirely relieved by a proper extract of corpus luteum, after other extracts were of no avail.

Most cases of sterility in women are due to gonococcal or other pyogenic infections, cervical stenosis or some other local cause. Occasionally, however, examination of a patient shows nothing pathologic in the pelvis. Under such circumstances it would seem that corpus luteum should be of decided benefit, because of its theoretical promotion of pelvic hyperemia. For example, a married woman of 31, in apparent good health, sought advice in March, 1913. She complained of scanty menstruation, prolonged intervals and sterility. She had two children, but was anxious to conceive again. Corpus luteum extract, in full doses, promptly increased the quantity of her flow and reduced the intermenstrual interval to about twenty-six days. She became pregnant the following July. This, of course, may have been simply coincidence, and I have not had the opportunity to prove otherwise by extensive experience with this class of cases, but it would appear that corpus luteum is not wholly without merit in enhancing the possibility of pregnancy in sterile women, particularly if used in conjunction with intra-uterine negative galvanism.

When one ovary has been destroyed or removed, or its function impaired, there usually occurs a compensatory activity in the remaining or healthy ovary. As a rule, this is sufficient to counterbalance the deficiency, analogous to the ability of one kidney to increase its functional capacity under similar circumstances. But at times, these supposedly and apparently healthy ovaries, for one reason or another, are incapable of assuming this added burden and fail to fulfil their mission. Corpus luteum is then indicated as a supplementary aid, and the results therefrom in these cases, with one exception, have been excellent. This exception was a young woman, a schoolteacher, on whom I operated some three years ago and removed a cirrhotic and hypertrophied ovary, containing a distinct cavity, lined with a false membrane, which had previously been the seat of an ovarian apoplexy, that had undergone spontaneous rupture and absorption. This patient exhibited all the nervous manifestations of an artificial menopause soon after her operation. She was put on corpus luteum extract and took it for a long time, but without effect, notwithstanding that her remaining ovary and all her other pelvic organs seemed to be normal at the time of operation. Her condition at the present time is but little improved, and this improvement followed the use of bromids and large doses of strychnin. In brief, the use of corpus luteum proved of no avail whatever, and this case constitutes a conspicuous failure.

One of two cases of repeated abortion, in which the cause was inexplicable, was carried to full-term labor by the use of corpus luteum extract. This patient had had eight abortions in six years of married life. She became pregnant in February, 1913, and was delivered of a healthy child the following November.

Corpus luteum will also be found of service in allaying the hyperemesis of early pregnancy. It has stood me in good stead on several occasions.

CAN A CORPUS LUTEUM EXTRACT REPLACE THE NORMAL FUNCTION OF THE OVARY?

Burnam stated in his paper[1] that he had "attempted to produce menstruation in three patients in whom the ovaries had been removed but the uterus left in. All three were given enormous quantities of luteum, but not one of them showed any sign whatever of menstruation." From this he concludes, that "when given by the mouth, even in very large quantity, the corpus luteum of the sow cannot entirely replace the normal function of the ovary of the woman, so far as producing menstruation is concerned." I have been fortunate enough to encounter a case controverting this evidence, and would suggest that had Burnam employed an extract prepared from the ovaries of pregnant animals only, he might have been favored with greater success in the cases he mentioned.

MENSTRUATION REESTABLISHED BY CORPUS LUTEUM EXTRACT AFTER BILATERAL SALPINGO-OOPHORECTOMY

Patient.—E. V. N., single, aged 22, was seen Sept. 25, 1912. Family history was negative. Patient's general health had always been good. Menstrual history was normal, except for one abortion a year ago. Last menstrual period occurred three weeks before patient was seen.

Present Illness.—About July 24 she noticed an indefinite pain in the left iliac region, which became progressively worse, and was accompanied by a thick, yellow vaginal discharge. There were no urethral symptoms. She then consulted a physician who, at the end of a week's treatment, advised her removal to a hospital. Her evening temperature was usually about 104 F., abdominal pain was severe, and prostration was marked. A general surgeon was called and advised immediate operation, but the patient and her attending physician refused permission. The patient remained in the hospital under palliative treatment and was discharged at the end of three weeks. She was told that her abdominal trouble was cured, but that her "gonorrhea" still required treatment. This was carried out by her physician in his office, but as some abdominal pain persisted and the discharge continued to be profuse, at the end of four weeks more she consulted still another physician, who referred her to me.

Physical Examination.—This showed a well-nourished and developed young woman. Temperature 99.6 F. (5 p. m.), and pulse 88. Heart and lungs normal. The vagina was filled with thick, yellow mucopus. Bimanual examination disclosed an immovable, anteverted uterus, the displacement being produced by what seemed to be two enormous pus tubes, matted together. The whole pelvis and its contents were agglutinated by a mass of plastic exudate, partially organized, which resulted from the concomitant peritonitis. Smears taken from the urethral meatus, vaginal orifice, and cervical canal all showed large numbers of intracellular and extracellular Gram-negative diplococci.

The preoperative diagnosis was gonorrheal endometritis and urethritis; bilateral pyosalpinx, with pelvic peritonitis.

The patient was ordered to rest for a few days, take frequent copious hot douches, keep the bowels well open, and an ice bag on the abdomen. Tampons of iodin-glycerin 10 per cent. were inserted in the vagina every other day until October 4, when I performed a laparotomy.

Operation.—The abdominal section was somewhat difficult because of the dense adhesions encountered. When the peritoneum was opened and omental adhesions separated, two large tumors, that looked not unlike baseballs, wedged in between the uterus and rectum, presented. These were what had been diagnosed as pus tubes on bimanual examination, but which were now recognized as ovaries. The preoperative diagnosis was not entirely incorrect, however, as a picturesque sausage-shaped pyosalpinx was curled above and around each one. The two ovarian tumors were cemented together posteriorly and were strongly adherent at the bottom of the iliac fossae. They were finally delivered unbroken, a double salpingo-oophorectomy was done, and the abdomen closed without drainage. The uterus was not curetted. The postoperative diagnosis was bilateral ovarian abscess and pyosalpinx.

Progress of the Case.—Recovery from operation was uneventful. As soon as the patient left the hospital, treatment for the gonorrheal endometritis and urethritis was instituted. These were completely cured in about four months, microscopic examination of a number of consecutive specimens having been negative. The patient was given 5 grains of corpus luteum extract, in capsules, three times a day, to prevent the occurrence of the unpleasant symptoms incident to the menopause, and not because the reestablishment of menstruation was anticipated. Sphygmomanometric and pulse readings were taken weekly. When the extract was commenced, Oct. 27, 1912, the pulse-rate was 90 and the blood-pressure 114. December 8, pulse 104 and blood-pressure 108. December 14, pulse 92, and blood-pressure 98. The corpus luteum was then stopped, and on December 21, after a week of rest, the pulse was 96 and blood-pressure 118. After this prompt blood-pressure recovery the luteum was begun again. On Jan. 2 and 3, 1913, the patient experienced slight backache and a sensation of fulness in the pelvis, and on January 4, she began a menstrual flow, which lasted three days. This flow was constant, although somewhat scanty. On January 29, she menstruated again for three days, more profusely than the first time. On February 26 and March 29, the duration of the flow was prolonged for five days each time. The capsules had been taken regularly until the latter date, except for short intervals necessitated by decreased blood-pressure. After the fourth menstruation, however, the patient was instructed to take the luteum only during the ten days immediately preceding the expected date of menstruation, as it was evident that the menstrual function was becoming firmly reestablished. That this view was justified was clearly shown by a report from the patient the following August, that she had menstruated for about five days every thirty days. She never suffered from any reflex nervous, sexual, or gastro-intestinal disturbances, and has apparently been well since her operation. She was last seen in October, 1913, and, as she expressed it, "was menstruating as regularly as before operation."

The specimens from this case were enucleated intact and have been preserved, and close inspection demonstrates beyond all question that no ovarian tissue was left in this patient's pelvis. I think that especially these two ovaries, in which all parenchymatous tissue has been destroyed and replaced by pus, with the integrity of their capsules preserved, are not without interest. Permanent continuance of regular menstrual periods in this patient, until she reaches the natural menopause age, cannot be predicted with positive assurance, but the recurrence of menstruation for even one year and the absence of unpleasant reflex symptoms are certainly encouraging. The only systemic disturbances from the organotherapy in this case were mild headache and vertigo for a few days; these quickly disappeared as toleration was established.

In addition to these interesting features, this case is an instructive one in other respects. This was evidently an extremely virulent gonococcal infection in the beginning and the patient was lucky to have escaped operation when the micro-organisms were most active, but she should certainly have had the benefit of operative interference as soon as the acute symptoms subsided. That was the ideal time, as the destruction of tissue was probably not as extensive then as it was a few weeks later. She was also fortunate to have escaped curettage or other intra-uterine meddling for the cure of her "gonorrhea." It will be readily appreciated that lack of extreme gentleness on bimanual examination, or the traumatism incident to dragging down the uterus before curetting, as is customary, might easily have ruptured one of these thin-walled collections of pus. Prominent bulging into the culdesac is certainly a great temptation to "incise and drain," but one can never be certain just what and how thoroughly he has drained. In this case, one or even both ovaries might have been drained, but both pyosalpinges might have been overlooked and remained and the patient's suffering would only have been prolonged.

CONCLUSIONS

1. Corpus luteum extracts are superior to similar preparations made from entire ovaries.
2. Suitable cases for corpus luteum organotherapy must be carefully selected.
3. The indications for the administration of a lutean extract are distinct and its use should be limited to these conditions.
4. The administration of corpus luteum is followed by certain definite phenomena.
5. It is of the utmost importance to use an extract obtained from the ovaries of pregnant animals only.
6. Five-grain doses, three times a day, are usually all that are required.
7. There is great necessity for constant supervision of the blood-pressure of patients taking corpus luteum. It should not be permitted to fall more than 15 mm. below the patient's normal pressure, and never below 90 mm.
8. Personal experience has demonstrated that corpus luteum organotherapy is of considerable value in clinical practice.
9. In one patient, menstruation has been reestablished after complete extirpation of all ovarian tissue, by the use of corpus luteum extract.

The Growth of Science.—Step by step as a science progresses the mass of knowledge composing it increases, the knowledge of the single items becomes progressively more accurate, and the methods for obtaining new results become more complicated and specialized. Therefore the efforts also of those undertaking research must be concentrated, that is to say, narrowed and specialized, otherwise the specialist will be wanting in technical capacity and in the means of carrying on his work with the best possible results.—Lugaro, Problems in Psychiatry.

USE OF CHOLESTERINIZED ANTIGENS IN THE WASSERMANN REACTION *

B. A. THOMAS, M.D., and R. H. IVY, M.D.
Professor and Instructor, respectively, in Genito-Urinary Surgery, Philadelphia Polyclinic
PHILADELPHIA

A great deal of work, experimental and other, is being done at present with various substances as antigens in the performance of the Wassermann reaction. This is tending so to vary the technic of the test and give rise to contradictory results as to create considerable confusion in the minds of those to whom the reports are of primary importance, namely, the clinicians. We thought it advisable, therefore, at this time to set forth briefly, without going too much into technical detail, our views of the antigen question based on a comparative study of different extracts.

Wassermann and his followers for a long time clung to the belief that the syphilis reaction was a true antigen-antibody reaction, between the *Spirochaeta pallida* on the one hand, and the specific substance produced by it in the patient's blood on the other. They were forced to modify this position by the discovery that alcoholic extracts of normal tissues, such as human and guinea-pig heart, could likewise be employed as antigens with good results. Nevertheless it is still held by Wassermann's followers that tissues rich in spirochetes, probably owing to the presence of substances produced by the action of the spirochetes, are superior as antigens to non-syphilitic tissues or synthetic products, and give the most reliable results in routine clinical diagnosis. We adhere to this view as the result of the use of syphilitic liver-extract in over two thousand tests, in which our results have differed in no material way from those of reliable workers.

This statement is made after a thorough trial of some cholesterinized extracts of guinea-pig heart and human heart, kindly furnished by Kolmer,[1] who, with Casselman, has recently reported favorably as to their reliability somewhat to the disadvantage of the syphilitic liver-extract. These extracts are made by saturating the ordinary alcoholic extract of normal heart with cholesterin, which is soluble in alcohol up to about 1 per cent. The cholesterinized guinea-pig heart-extract was used by us along with our own antigen of alcoholic extract of syphilitic liver in the routine examination of 100 cases, the cholesterinized human heart-extract being employed in thirty-three cases. These investigations covered a period of several weeks. We may say here that the difference in results with the three antigens was no more marked at the end of the period during which these comparative tests were made than at the beginning, so that they cannot be ascribed to deterioration of the extracts. Careful preliminary titration of the antigens was carried out before doing the tests, and at no time was more than one-third of the anticomplementary dose used. The comparative results of tests with syphilitic liver-extract and cholesterinized guinea-pig heart-extract may be divided into four groups as follows:

1. In twenty-two cases the results were positive with both antigens, with little or no difference in degree of reaction.
2. In eight cases the syphilitic liver-extract gave a weakly positive reaction, while the cholesterinized extract gave a stronger reaction.
3. In thirty-six cases both antigens gave a negative result.
4. In thirty-four cases the syphilitic liver-extract gave a negative reaction, while the cholesterinized heart-extract gave a weakly positive or medium positive result. This is naturally the most important group from the clinical point of view. Nine of these thirty-four cases were treated cases of syphilis exhibiting no symptoms, showing that it is more difficult to render the serum negative to the cholesterinized heart-extract by antisyphilitic treatment. The remaining twenty-five of this group were cases submitted for diagnosis or which had no signs or history of syphilis. When one antigen reacted more strongly than the other, it was always the cholesterinized heart-extract. In no case did the syphilitic liver-extract give a stronger reaction than the cholesterinized extract.

In the comparative tests with the cholesterinized extract of human heart, of thirty-three cases there were six in the first group, that is, equally positive with the two extracts; four in the second group, in which the cholesterinized human heart-extract gave a distinctly stronger reaction than the syphilitic liver antigen; sixteen in the third group, in which both antigens gave negative results; seven in the fourth group, which were negative with the syphilitic antigen but positive with the cholesterinized heart-extract.

In the first series, therefore, the results with the two antigens disagreed in forty-two out of 100 cases, and in the second series in eleven out of thirty-three cases. We see from these results that the cholesterinized extracts apparently give a more "delicate" reaction than the extract of syphilitic liver, but we also find that many weakly positive results are obtained by them in non-syphilitic cases. This fact alone is quite sufficient, in our opinion, to offset any advantage in delicacy of the reaction obtained with the use of cholesterinized extracts. We feel that just as high a percentage of positive results is obtained in known or clinically apparent syphilitics with the syphilitic liver-extract as is obtained with the cholesterinized antigens, and the former do not give positive results in non-syphilitic cases. The success in detecting mild degrees of syphilitic infection is doubtless due in part to the use of one properly standardized unit of complement and hemolytic amboceptor, as suggested to us by Laird,[2] instead of double or triple units as employed by many workers. We must conclude that with cholesterinized antigens, varying degrees of inhibition of hemolysis may be obtained in serums from many conditions other than syphilis, and in normal persons. While experimental investigations are to be highly commended, we therefore regard the employment of these artificial antigens for routine clinical use at the present stage of our knowledge, instead of being an advance in serologic technic, rather as a distinct step backward.

Schamberg, Kolmer and others[3] report that they obtained positive Wassermann reactions, using the cholesterinized antigens in over 28 per cent. of twenty-two cases of psoriasis, in a great many of which syphilis could almost certainly be excluded, thus providing evidence that weak reactions with these antigens do not necessarily mean syphilis, and that a diagnosis of syphilis cannot be based on weak and medium inhibitions when they are employed. We hold that weakly positive reactions with syphilitic liver-extract mean nothing but syphilis. Even though it were true that the cholesterinized antigens give a more delicate reaction and may furnish positive results in cases of syphilis that are negative to the syphilitic liver-extract, it is a very much less serious error to overlook an occasional case of syphilis than to saddle a diagnosis of the disease with all it entails on a patient who does not have syphilis.

Considerable harm is being done at present by the use of unreliable non-specific or artificial extracts, in two ways:

1. The marked discrepancies between the results of the Wassermann test and the clinical findings in many cases are causing skeptical clinicians to lose confidence in the value of the reaction, and thus they are being deprived of an important diagnostic and therapeutic aid.
2. A great many unfortunate persons are being treated for syphilis who have not and never had syphilis, as the result of weakly positive and doubtful reports of workers using these antigens.

By all means let the experimental work go on, in the endeavor to improve the technic of the Wassermann reaction; but until the results obtained with innovations are proved to be more reliable than those with the generally accepted methods, let us adhere to the technic and reagents that have withstood successfully the assaults of time and which are supported by clinical experience.

INCREASE IN TOXICATION OF ETHER BY NEW METHODS OF ADMINISTRATION

RAYMOND C. COBURN, M.D.
Anesthetist, New York City and New York Post-Graduate Medical School Hospitals; Supervising Anesthetist Beth Israel Hospital
NEW YORK

The small amount of ether administered in the intravenous method, as compared to that used in the inhalation and insufflation methods, has led some to believe that this direct method of introduction lessens the amount of ether utilized by the patient in the maintenance of anesthesia, whereas the reverse is true. Anesthesia is maintained by keeping the ether and the blood at a certain ratio. When the blood remains constant in volume, increase or decrease in the percentage of ether deepens or lightens the anesthesia accordingly, and conversely, the amount of ether within the system remaining constant, an increase in the volume of the circulating fluid decreases the depth of the anesthesia. To maintain surgical anesthesia in the intravenous method, then, the amount of ether required is increased in the proportion that the saline solution bears to the original, total volume of blood.

In the normal adult (150 pounds) the amount of blood varies from 4.58 to 4.65 liters, and from this can readily be calculated the extra burden of ether toxication thrust on the patient. In such a patient, using preliminary hypodermic medication, intravenous administration requires for induction about 8 ounces of saline solution; that is, at the end of induction there is being thrown into circulation about 5 per cent. more ether than is required in other methods; at the end of an hour's surgical anesthesia the excess is 15 per cent., and at the end of a prolonged operation, in which it is reported that 4¼ pints of saline solution were administered, the excess was more than 40 per cent.

It is futile to hold that this pronounced excess of ether does not increase ether toxication. While some of the saline solution transudes into body cavities and tissues, it carries ether with it, and this must subsequently be excreted. The comparative freedom from postnarcotic nausea and vomiting does not necessarily indicate lessened ether toxicity, for the methods of administering ether that avoid passing a strong vapor continually over the olfactory nerves are likewise followed by less nausea and vomiting. The odor of ether, *per se,* is nauseating, and causes much of the vomiting in the cruder methods of administration.

In the oil-rectal method of administering ether the same ultimate result — increasing the amount of ether in circulation — seems to follow, although the modus operandi is entirely different. Here, in the adult, about 6 ounces of ether, plus 2 ounces of olive-oil (both by volume) are introduced into the rectum. All of the ether thus introduced reaches the patient's circulation, except that which is subsequently withdrawn, as there is no source of evaporation, such as occurs in other methods. It requires only 1½ ounces of ether in the patient's circulation without rebreathing to induce and maintain an hour's surgical anesthesia. The amount of ether withdrawn in the oil-rectal method shows that a much larger amount than this reaches the patient's circulation. The much larger amount of ether required in this method is probably due to the oil interfering with the anesthetic action of ether. Theoretically, of course, this is true, and it seems to be verified practically. Not only is there very much more than 1½ ounces' difference in the original amount of ether introduced into the rectum and that withdrawn at the end of an hour of surgical anesthesia, but there is a decidedly greater tendency toward respiratory paralysis without the corresponding depth of anesthesia that occurs in other methods. This indicates that while the oil may lessen the anesthetic action of ether it does not correspondingly decrease its toxic action on the respiratory center. Certain it is that the margin of safety between surgical anesthesia and respiratory paralysis is considerably reduced in the oil-rectal method.

It is not contended that these methods are without value, for each possesses decided advantages; but the price that is exacted for these advantages should always be given proper consideration.

VAGOTONY AND ITS RELATION TO MUCOUS COLITIS

B. L. SPITZIG, M.D.
CLEVELAND

The classical work of Eppinger and Hess in recent years materially advanced our knowledge of visceral neurology. Through their initiative a more thorough investigation of the relationship existing between the nervous supply and visceral function was instituted, and this investigation has resulted in clarifying hitherto obscure problems pertaining to this subject. In many complex disorders, particularly those dependent on changes in the glands of internal secretion, there is a change of tonus in the two important systems, the autonomic[1] and the sympathetic. The former comprises chiefly the oculomotors, the vagi and pelvic nerves. An overaction of this system is shown in certain cases of ulcer, bronchial asthma and pollakiuria, whereas in exophthalmic goiter and diabetes mellitus the effect of the sympathetic predominates. It is supposed that in certain states there may be an insufficiency of the one system or a hyperplasia of the other; and again, it may happen that both systems hypofunctionate or hyperfunctionate coincidently.

Clinically, disorders of the vagal tract are the easiest to understand, and this paper will deal chiefly with hypertonicity of that system (vagotony). On account of the anatomic distribution of the nerve, symptoms of increased innervation are readily identified in the gastro-intestinal tract. Perhaps the most constant result of such activity is the state of hypertonus in the musculature of the stomach and intestines. The bowel, chiefly the colon, remains in a more or less constant phase of overcontraction. This condition is demonstrable in that type of constipation, referred to as spastic, which is frequently found in early and middle adult life. The tender, palpable colon is a prominent sign of vagotony, as well as the frequent presence of a tightly contracted external sphincter. Rectal palpation furnishes valuable aid in identifying this state of hypertonicity and should never be omitted. The complaint of abdominal pain is a frequent, but not necessarily a constant occurrence. In cases of pronounced spasticity patients complain of intermittent pain in the locality of the large bowel. Commonly, the transverse part is affected from the right to the left sides, which phenomenon arouses visions of cholecystic, duodenal or gastric lesions. Often the pain is referred to the cecal region, and this circumstance is responsible for the removal of countless innocent appendixes. The descending colon is involved in most instances in which pain is a prominent symptom and is most likely to show evidence of spasticity—a valuable feature in differentiating from chronic appendicitis and other common abdominal lesions.

Many cases in which colic occurs are complicated by other colonic anomalies, pericolic membranes, kinks and ptoses. This relationship has been discussed in an earlier communication.[2] The interesting point is that many patients complain of abdominal pain which is characteristic in its location and often in its relation to defecation, occurring usually before and after the evacuation of the lower colon. Sometimes this pain occurs after taking cold drinks or after too rapid eating, when it is followed by a profuse, mucous evacuation, the "nervous diarrhea" of former writings. Nicotin seems to have some relation to this disorder, for excessive smoking and chewing may result in attacks of colic. Possibly it acts as an irritant to the vagus, as does lead in cases of plumbism.

The number of patients showing the absence of abdominal pain is equally large, but this does not militate against the existence of hypertonicity. Physical examination usually elicits evidence of varying degrees of tenderness and palpability of the large bowel. A careful abdominal examination and palpation of the rectal canal show the existence of this condition when it was least expected from the anamnesis. The frequency of the disorder is astounding; perhaps two-thirds of young adults are sufferers at different times. Commonly, a history of the cathartic habit justifies the suspicion of the probable existence of colonic spasm, as most cases of resistant constipation in early adult life are proved to be spastic in character.

The influence of vagotony is referable to changes in the stomach. Delayed evacuation of the gastric contents frequently indicates pylorospasm, which results from overfunctioning of the vagus. With this factor hyperacidity is usually concomitant — a group of signs very suggestive of ulcer. Indeed, it is supposed that the ischemia from muscular spasm and an excess of acid, together with a possible infectious cause, may lead to ulcer formation. Perhaps most gastric ulcers that have been permanently relieved by medicinal measures were no further advanced than the stage of pylorospasm and hyperacidity. Other gastric neuroses, cardiospasm and singultus, may further suggest the diagnosis of this condition.

The cardiac system may present the signs of bradycardia and occasionally mild arhythmia. The lungs sometimes offer confirmatory evidence of vagotony in the occurrence of attacks of bronchial spasm or a tendency to sighing with forced expiration. The rarer signs of increased vagal innervation are miosis, salivation, increased perspiration and urination, facial flushing and cold extremities.

Within the last year a pupil-test has come into vogue. On forced inspiration the pupils are dilated and contract on expiration. Similarly, the pulse is quickened and slowed during the same respiratory phases. Both these tests, when positive, indicate vagotony. In the limited number of cases tested in personal work more than half showed positive results. It was found that the pupil-test sometimes fails when demonstrated too often in rapid succession.

There is little difficulty in recognizing pronounced cases of vagal overstimulation; but there are other conditions, not so outspoken, which respond to the appropriate treatment and can possibly be included in that category. Status lymphaticus, for instance, has been treated with success through measures directed toward controlling vagal activity. Mucous disease of childhood shows a certain relation to the last-named. The pasty anemia and exudation of the skin are characteristic. Abdominal pain and distention, clay-colored stools with excess of mucus, marked irritability and asthenia complete the picture. Bronchial spasm and lymphatic hyperplasia sometimes occur. Errors in diet, an excess of starchy and coarse foods and a lack of proteins seem to be causative factors and may induce the clinical picture by stimulating the vagal system. This chronic intestinal indigestion readily responds to dietetic and medicinal treatment that relieves such overstimulation.

In mucous colic of adults there may be a similar relation to vagotony. The cause of this disorder does not lie in the intestinal mucosa, as there is usually no evidence of a colitis. The lesion is more central and may have its site, at least in the early stages, in a disturbance of the autonomic system. The hypochondriasis suggests that the sympathetic as well as the autonomic system is involved. In this neurosis chronic constipation precedes and attends the disorder, and it is conceivable that this factor induces an overstimulation of the vagus (probably through the internal secretions) and later of the sympathetic system in cases of inherited or even acquired nervous instability. The fact that many patients suffering from mucous colitis give a history suggestive of prolonged intestinal spasm is important. The seasonal recrudescence also is interesting. Attacks occur periodically after a season of intensive application to work, during which time intestinal and general hygiene are neglected through attention paid to other duties.

---

[1] The term refers to the essential autonomic system. Some writers include both systems under autonomic and distinguish them as the sympathetic autonomic and the craniosacral autonomic or autonomic proper. For the sake of brevity the simpler terms are used.

[2] Spitzig, B. L.: Intestinal Intoxication and Thyreotoxicosis, Ohio State Med. Jour., 1913, ix, 408.

In a short series of these cases the pharmacodynamic methods[3] yielded interesting results. Two-thirds of these patients reacted severely to epinephrin, thus indicating increased sensitiveness of the sympathetic system. Nearly all tolerated large doses of atropin, which factor suggests that vagotony was present. The pilocarpin test was not constant in results.

MODE OF TREATMENT

In relieving vagotony, belladonna and its active principle are the remedies *par excellence*. Hyoscyamus and opium are sometimes useful, but do not compare with the first-mentioned drug. As a routine treatment, a dose of 5 drops of the tincture or 1/6 grain of the extract is ordered three or four times daily, and is continued until the symptoms of dry throat and mydriasis appear. The dose is then decreased and thereafter varied to suit the individual tolerance. Occasionally there is marked idiosyncrasy toward the remedy, but the apparent relief from vagal disturbances outweighs the irritation from the drug. Medication is continued for one or two weeks, until all abdominal soreness has disappeared and tenderness is no longer evoked by palpation of the affected colon. After an intermission of two weeks another course of belladonna is advisable in resistant cases.

The correction of constipation is very important, but the methods used must in no way aggravate the spasticity. Consequently, massage, severe bending exercises and iced applications are decidedly contra-indicated. Similarly coarse food and laxatives as aloin, senna, rhubarb, podophyllin and violent salines are to be avoided. The mildest drug is phenolphthalein, but a more natural laxative is the undigested sea-weed agar-agar. This seems most helpful in 1-dram or 2-dram doses after meals, until the dietary can be enlarged to include more cellulose. The diet is general in character — proteins, carbohydrates and fats are allowed, provided there is no contra-indication to any class of these foods. Fruits and tender vegetables are permitted, and as the colonic irritation subsides the coarser foods are added to the dietary. The habit of regular defecation is to be emphasized at the outset of treatment.

Mucous disease of childhood demands special consideration. In this condition agar and belladonna are of great service in hastening the disappearance of the abdominal symptoms. Dietetic modifications are needed in the reduction of starchy products and the withdrawal of all foods coarse in structure and irritating to the tender intestines of the child. Proteins rich in iron are useful and a moderate quantity of fats. Coffee and tea naturally deserve denunciation. Regular meals are to be prescribed with a minimum of liquids, and lunches of starchy foods and sugars omitted. The tender fruits are allowed, and as the condition improves other cellulose foods are added.

The treatment of mucous colitis is the most difficult of all. Many patients show earlier gain with insistence on absolute rest, physical and mental. Two weeks' rest in bed is time well spent. During this period the regimen of treatment can be properly inaugurated. Hot abdominal compresses are always beneficial and can be ordered best during the period of confinement in bed. The diet is of no mean importance in mucous colic. For several days the food is bland and non-irritating, but of high nutritional value. As soon as possible general diet is ordered and forced feeding is instituted to continue far beyond the time of convalescence. There is no more abstemious eater than the neurotic with mucous colitis. Usually he has dieted himself to the verge of inanition, and his lack of food tolerance is more mental than physical. As soon as he is carried to a stage at which he realizes that an abundance of food is beneficial, he acquires his full share of self-confidence and his progress is assured.

The medicinal treatment has been suggested before. Belladonna is ordered in full doses. In severe cases morphin is combined with atropin. A capsule of opium and belladonna, each ⅛ grain, and ½ grain of phenolphthalein is given four times a day, the laxative preventing self-medication. The use of belladonna is sufficient in milder cases that seem free from intense sympathetic stimulation. In the latter event a capsule of calcium lactate, 5 grains, and extract of ergot, 2 grains, given four times daily, seems to have some effect in quieting sympathetic excitation. When this fails, opium is used, as indicated above. Other measures are of less importance. Agar is ordered in place of coarse diet, and olive-oil is given internally. Liquid petrolatum does not seem superior to cottonseed-oil, and castor oil may be of some benefit. The question of the value of enemas is undecided. Olive-oil or a starch solution injected into the bowel can do no harm. Some patients judge the ability of their medical attendant by comparing his methods with those of his predecessors. It may be diplomatic not to omit intracolonic injections of oil, but astringent solutions of various kinds are idle therapeutic measures.

Complete restoration of vigor after an attack of mucous colic may be retarded over a variable period. It seems, however, that by recourse to this intensive treatment the time of convalescence is materially hastened. After all is done it sometimes happens that complete relief is obtained ultimately through a change of environment. A sojourn at the seashore often precludes the necessity of resorting to colostomy or colectomy, procedures extremely doubtful as to their permanent worth.

I acknowledge the many courtesies extended by the clinical staff at the Charity Hospital Experimental Department of Western Reserve University.

Psychasthenia.—Psychasthenia is always congenital by virtue of the heredity which outlines the characteristics of our brain.—Dubois.

---

[3] In explanation of these tests it may be stated that epinephrin (1 c.c. of a 1:1,000 solution) indicates a positive reaction by the onset of chills, arrest of secretions, marked tremor, mydriasis, tachycardia, intense headache and vertigo (from increased cerebral pressure). Pilocarpin (from 1/10 to 1/15 grain) is used to indicate autonomic sensitiveness and shows a positive response (usually when sympathetic hypertonus is absent?) by the occurrence of flushing, increase of all secretions, miosis, bradycardia and syncope (from cerebral vasodilatation). When atropin is tolerated in large doses (from 1/75 to 1/150 grain) and can be continued for long periods before the physiologic effects are obtained, the existence of vagotony bears confirmation; at least the untoward symptoms, xerostoma, mydriasis, tachycardia and precordial distress, encountered when the tonus of normal vagi is depressed, are not so readily induced in subjects presenting clinical signs of vagal overstimulation. An exception to this statement appears in those cases in which there is evidence of coincident sympathicotony. It appears that in this situation the sympathetic needs to be depressed (calcium, ergot, morphin) and the larger doses of atropin are thereby tolerated.

URETERAL OBSTRUCTION CAUSING URINARY STASIS

A NEW ETIOLOGY IN KIDNEY-STONES, WITH A NEW METHOD OF NEPHROPEXY TO SECURE IDEAL NATURAL DRAINAGE *

O. S. FOWLER, M.D.
DENVER

So many factors have been adduced in the etiology of kidney-stones, and so many differences of opinion on these various factors have been current among men of high authority, that this condition seems somewhat analogous to the diseased conditions which have so many remedies offered for them that none of them is likely to be of value. Thus, the theory held by many that disturbances in the digestive processes and in the general metabolism of the body are etiologic factors seems to have been fairly well supported, but Watson and Cunningham state that the correctness of this view is now doubted. Dr. A. B. Johnson puts it lightly by saying that "in general, defective metabolism from any cause seems strongly to predispose to renal calculus." He further says that mode of life, apparently, has some influence; a sedentary life, a nitrogenous diet and the use of alcohol seem, in some cases, to determine the formation of renal calculus. On the other hand, among persons who live chiefly on carbohydrates and who live and work vigorously out of doors, renal calculus appears to be quite common enough.

Keyes puts it rather tersely by saying that the etiology of primary kidney-stone is most obscure. He later elaborates on a course of preventive treatment, but admits that he bases few hopes on it.

The older writers, according to Mumford, included nephrolithiasis under the term "gouty diathesis"; but Watson and Cunningham observe that "among the natives of certain provinces of India, joint manifestations of gout are not known to occur, but that calculus disease is extremely prevalent. These people are vegetarians and abstainers from alcoholic stimulants, and the facts cited are in direct contradiction to the idea of the injurious influence of meat diet, alcohol, etc., or at any rate serve to show that among the natives of this race these factors play no part in calculus formation, *which must be referred to some other cause.*" This view is further supported by the statistics of Surgeon-Major Roberts of the English Army, based on 3,041 operations for kidney-stone in India in the course of one year, in which country alone, seventy-eight of each thousand inhabitants were operated on for this condition. Guiteras states that it occurs more often in men than in women, but Ransohoff in Keene's "Surgery" says that it is equally common in the two sexes. Reclus and Duplay also make the same assertion, while Schenk and Tenney report the figures for 134 cases of which seventy-four were *in women and fifty-eight in men.*

The statistics of these calculi show that approximately one-half are of uric acid; but uric acid stones do not usually show by roentgenoscopy, and the roentgenologists maintain that not over 2 to 5 per cent. of all stones fail to show by present methods: thus it would appear either that there is much variance in the figures, or that the stones are not pure uric acid, but are combined with other minerals which cast a roentgenographic shadow. Concentration of the urine as predisposing to deposition of its salts is a factor agreed to by practically all writers; thus, the concentration of the urine by perspiration *would seem to be a factor;* but, on the other hand, kidney-stones are very infrequently found in the negro race, on the whole to be regarded as a tropical people.

There is more uniformity of opinion on the question of local causes, for more definite information may be had on various objects which act as a center of crystallization, such as foreign bodies, blood-clots, masses of mucus and pus, micro-organisms and parasites and certain drugs which by their irritation produce sufficient desquamation of epithelium and excretion of mucus to serve as the nucleus.

Fenwick, Guiteras and others have mentioned that stones are sometimes found in movable kidneys, but apparently they do not regard this as any more than simply a predisposing factor. It is generally agreed that a stone may at first be primary in origin, but may have secondary depositing layers of other materials in consecutive strata and that this is usually the course, which would again indicate that pure uric acid or other pure stones are in reality found less often than we might be led to believe from many of the statistics on the subject. Pyonephrosis is usually regarded as secondary to stone formation and obstruction. It is certainly true that the stone does increase the infection, but I believe that the opposite is true originally before the stone was formed.

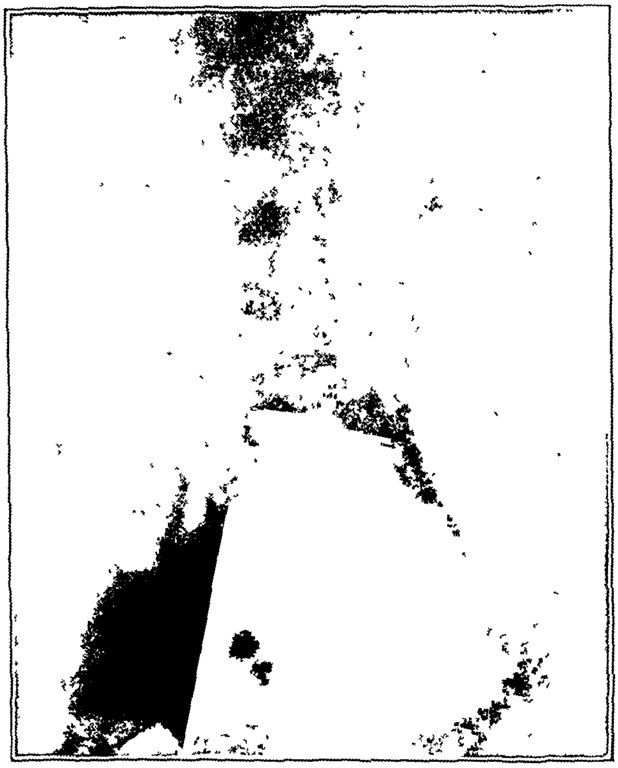

Fig. 1.—Mrs. C. G., referred by Dr. Robert King. A normal kidney and ureter on the left side are shown with patient standing. Kidney is slightly down but there is no rotation and the ureter has *no angulations. The gentle deviations in its course are normal.* The calices are clear-cut and normal. The right kidney is in the pelvis and rotated 90 degrees, with its pelvis pointing upward. A sharp angulation or kink opposite the fourth lumbar vertebra gave rise to an intermittent hydronephrosis, the obstruction which is presented in this paper as the basic etiology of kidney stone. This obstruction gave rise to a transferred pain to the left ureteral region, one of the few proved cases of transposed kidney pain.

It would seem, *therefore, that there* is almost no point in the general etiology of primary kidney-stones that all are agreed on, with the exception of concentration of the urine, so it appears that we are certain of little in this interesting and important subject.

---

* Read in the Section on Genito-Urinary Diseases of the American Medical Association, at the Sixty-Fourth Annual Session, held at Minneapolis, June, 1913.

I wish to call attention to a condition in the urinary tract which appeals to me as being a reasonable etiologic factor and one which might add much to our present indefinite knowledge on the subject, if properly and carefully sought. I was astonished several months ago, while going over a large amount of roentgenographic material, to notice that those cases in which the patient now had a stone in the tract or had given a positive history of having passed a stone and recovered it from the urine, all showed an obstruction in the course of the ureter to the free outflow of the urine. This point I have endeavored to demonstrate in each case since, with such results that now I expect to find it. To date I have secured the records of six cases with sufficiently good plates for reproducing on lantern-slides. These are not all the cases seen, but all in which I was fortunate enough to have the privilege of completing the diagnosis.

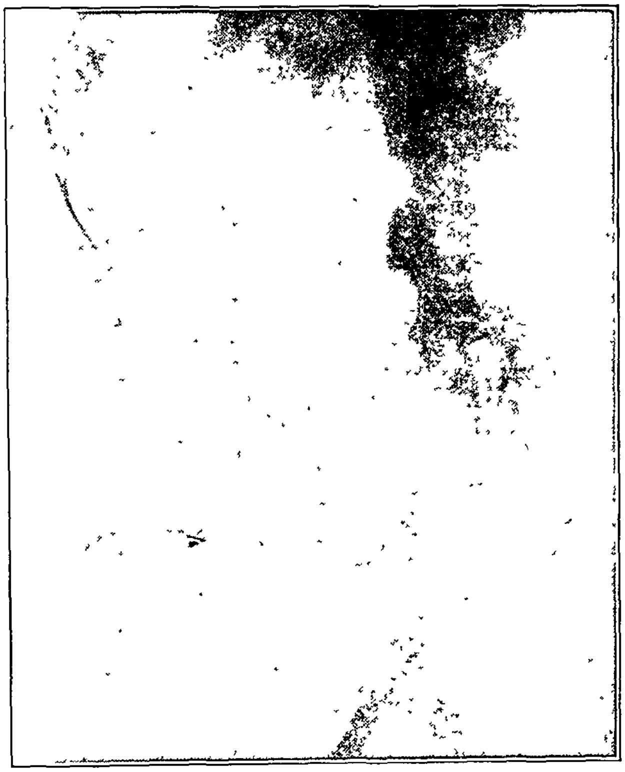

Fig. 2.—Mr. C. V. Z., young man, referred by Dr. Van Zant. The patient is standing and the roentgenogram shows right kidney dropped only the width of one vertebra. There is a stone-shadow in the pelvic portion of the ureter Opposite the lower fourth lumbar vertebra is a distinct angulation; collargol is entirely pinched out. This obstruction gave rise to an intermittent hydronephrosis on which was implanted a colon infection. There were occasional attacks of pain, blood and pus Kidney pelvis is convex on lower border. Calices are not clear-cut and definite on their edges. Operation was performed, at which stone was removed from ureter, and nephropexy done.

By way of introduction I wish to call attention to the fact that in all four-footed animals, and in man when on all fours, or on the abdomen, if the kidney is in its proper position and has sufficient anchorage, of a series of horizontal planes drawn through the animal lengthwise those passing through the body of the kidney in its parenchyma would be the highest, and those passing through the mouth of the ureter would be the lowest part of the tract, and the bladder would lie yet lower than this. Thus it can be readily seen that under these conditions the urine has a down-hill drainage until the bladder is filled, and then the viscus empties itself upgrade by sufficient muscular activity. The ureter is supplied, as is well known, with muscular fibers which give intermittent spurts of urine into the bladder, but the kidney and the upper portion of its pelvis are not supplied with this musculature; therefore, the kidney and pelvis must empty themselves by some other method, and it is evident that when mankind assumed the upright attitude, the normal kidney drainage suffered to this extent, that the lower calix or calices are below the lowest part of the kidney pelvis as it leaves the kidney and that this naturally gives a space in which there must always be at least some stasis of the urine. Whether or not this reasoning is correct, however, in regard to the normal kidney, future investigations will undoubtedly give much definite light on the subject. We do know, however, that there is stasis of the urine in those kidneys that have obstruction in the ureters, and it is this evidence that I desire to present. We know that the kidney has suffered, along with most of the other abdominal and pelvic organs, by the assumption of the upright attitude and that it is insufficiently supported to maintain its proper position and relation and is prone to descend from this position in both men and women about equally, if examined roentgenographically; we also know positively that stasis invites and harbors infection, whether it is within or without the body; this is true of gall-bladder stasis, regarding which it has been conclusively proved by Naunyn that there are but two necessary conditions for the formation of gall-stones, infection and stasis, that stones will not form in a sterile medium even when a sterile foreign body is introduced (smooth, round ivory balls), that the cement substance is supplied by the inflammatory process and that the inflammatory debris acts as the nucleus around which the stone grows.

The same conditions of stasis and infection are the recognized requirements for primary stone formation in the urinary bladder, and the findings to date demonstrate that the same conditions are present in the formation of primary as in the formation of secondary stones in the kidney. Dr. Guy Hunner has recently made the statement that he believes that pyelitis occurs only in the presence of more or less obstruction, and I have much positive roentgenographic evidence of this, in addition to the clinical evidence in the pyelitis of pregnancy, a well-recognized lesion due to the pressure of the fetal parts on the ureter, which usually clears up after delivery, provided that this is the only cause of obstruction and that some urinary stasis had not existed before the pregnancy which had not been sufficient to give a marked degree of urinary obstruction. Many women, however, date kidney difficulty from the time of a pyelitis of pregnancy, which did not or could not clear up afterward.

It seems to me that the main reason for the tardy recognition of this apparently important etiologic factor has been that until recently it was necessary for the profession to depend on the clinical findings and on the operative and post-mortem findings when the lesion had advanced so far that its origin was hidden beyond recognition by the extensive secondary destruction. Now, with cystoscopy and roentgenoscopy, we are able to demonstrate even the mildest degree of obstruction in the urinary tract and to offer proper relief long before marked loss of functional ability has occurred. It has been asserted by some general surgeons that they can diagnose these urinary conditions without the aid of the cystoscope and the Roentgen ray; but to me such a statement is only proof positive of ignorance of modern diagnostic procedures, as well as a vicious carelessness of the patient's welfare, which depends largely on accurate diagnosis.

As stated previously, the roentgenograms show the presence of a stone, or one was passed and recovered; and they also show ureteral obstruction. Which lesion was the earlier in the patient's history, the stone or the obstruction? We well know that motility of the kidney with a small amount of obstruction may exist for some time without giving serious difficulty or perhaps being recognized, but a stone does not act so kindly; it usually gives early positive evidence that it is there and will stay there until something of a radical nature is done to remove it. Another point in favor of the obstruction theory is that we know that all substances in chemical or physical solution are hastened in precipitation and deposition of sediment by being at rest (stasis) or in a slowed stream; for we do occasionally have stones in the kidney without infection which are, almost without question, deposited there chemically as crystals and cause sufficient irritation to produce mucus which acts as a cementing substance. This theory also accounts for the fact that the vast majority of kidney-stones are found in the lower pole or in the pelvis of the kidney. Stone in the upper pole is unusual and stone in the parenchyma is a surgical rarity according to a number of authors. It also accounts for the formation of a nucleus by the presence of more or less infection and inflammation, producing pus, mucopus and even blood-clot.

These evidences and arguments I submit to the judgment of the profession, but I believe that all will agree with me that the previous theories are insufficient, that some of them are so far-fetched as to be absurd, and that this theory offers the same evidence that is demanded in regard to the formation of stone in other hollow viscera.

So much for my own experience with this lesion. I believe that its presence can perhaps be demonstrated in all cases of stone in the urinary tract or in cases in which there has been stone, if the method[1] of diagnosing intermittent hydronephrosis prepared and presented by me two years ago is used. I should be pleased if doctors, when examining cases of this sort, would keep this point in mind and try to add more evidence to prove or disprove my explanation of the coexistence of these two lesions, which appears to me as most reasonable and has thus far been demonstrated in all of the cases in which I have been fortunate enough to secure satisfactory roentgenograms.

There is only one method of treatment of the stone, and that is to remove it. Nothing has ever been said, however, about removing the local causes of pyelitis and guarding against the recurrence of the kidney-stone, except that some advice has been given as to diet and the general habits of life, all without much hope of accomplishing anything. There is a principle in general surgery that in order to cure an infected cavity or abscess, complete and thorough drainage must be established; one does not expect a gall-bladder to recover until it has been drained or removed, or an old man to have clear, sterile urine so long as there is a puddle of retained urine in the bladder. Neither do I believe that a pyelitis or a pyelonephrosis can ever clear up so long as the cause, ureteral obstruction, is not removed or prevented; I do not believe that the possibility of a recurrence of kidney-stone is removed so long as, after removal of the present stone, provision is made only for temporary drainage of the infection. I therefore suggest that the following method of nephropexy be used in kidney infections of this sort:

I wish to call attention again to the statement that the lower calices are improperly drained even in the normal position of the kidney. It occurred to me, therefore, that if the kidney were rotated upon its anterior-posterior axis during nephropexy in such a manner that the upper pole was drawn inward and downward and the lower pole drawn outward and upward to such a position that the lower calix would be on a level with or beyond the upper calix, the patient, when in an upright position, would have downward gravity flow of urine from the lower as well as from the upper pole, and that this position would fulfil the demand for a permanent free drainage of the kidney in all parts. I concluded on trial that it would be impossible to accomplish this task with the usual method of nephropexy, as the capsule is so fragile that it will not, in its normal position, support the organ properly by any method.

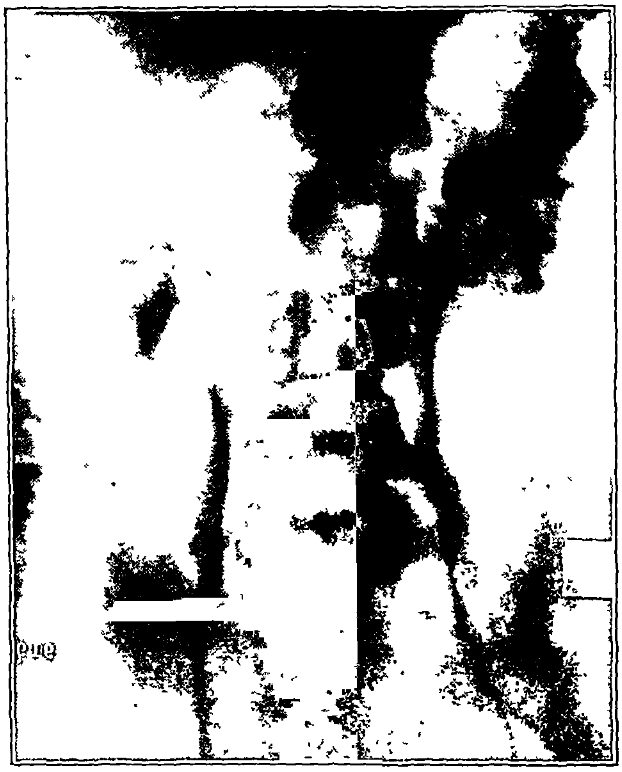

Fig. 3.—Mrs. C. J., standing. Both kidneys are dropped, not markedly; left shows marked angulation 1 inch below pelvis; collargol is entirely pinched out. Patient has passed kidney stone following attack on left side; has had similar attacks in right kidney region but never a stone passed; these continue. The right kidney shows slight rotation; at convex lower border of pelvis, shadow of ureter can be seen passing through the shadow of pelvis; calices are not well defined on their edges; there is some pus with colon bacilli from each kidney; no stone shadows were shown in tract. A diagnosis of double intermittent pyohydronephrosis was made and verified by later exploratory operation for supposed stone, done by another surgeon. Patient was not relieved following this, but at last report, nearly two years later, was steadily improving.

I found that it would be necessary to obtain and use some stronger material for this purpose; I determined on a trial of strips or thongs of fascia lata, one to be used around each pole of the kidney in the following manner: While I am operating on the kidney my assistant removes the fascia from the leg by making an incision about 8 inches long in the front and outer aspect of the thigh and removing a strip of the fascia lata 1 inch wide and about 11 inches long. This I divide lengthwise, making two strips each ½ inch wide. These are put in warm salt solution until needed. This fascial wound is closed with catgut and figure-8 sutures of silkworm gut. I then expose the kidney by the usual oblique incision, without dissecting off the nephrocolic ligament, clear the capsule in the usual manner and free the ureter to remove the cause of the obstruction, the location of which has previously been demonstrated by roentgenoscopy. I next make a series of incisions through the capsule each about ⅝ inch in length around the kidney at about the junction of the thirds of the kidney (see illustration); I now lift up the capsule between the alternate incisions and weave the fascial strip through these, leaving the ends free. I do this by beginning closer to the pelvic border with the upper pole and closer to the outside border for the lower pole, for the purpose of giving the proper direction of traction to obtain the desired rotation of the kidney when the fascial strips are brought through the muscles of the back with a large hemostat adjacent to the wound edges. The one from the lower pole is brought out immediately above or below the last rib and the upper one close to the spine just about on a right-angled line from the spine to the outer one.

---

[1] Fowler, O. S.: Tr. Colorado State Med. Soc., 1911.

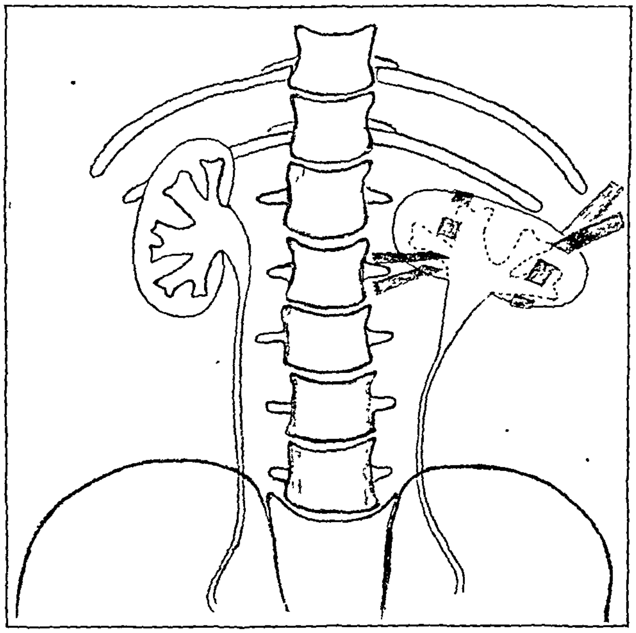

Fig. 4.—The author's method of nephropexy.

I first did this operation nine months ago and have now performed it thirteen times on eleven different patients, with no difficulty following from the transplanted fascia. In every instance except one I have closed the opening in the fascia lata, but I do not think this at all necessary as I believe that a hernia of the muscle will follow only through a slit, and not through a broad opening. It may be asked what becomes of the fascial strips in their new location. I do not think that they become absorbed, as does catgut, but, since they are composed of autogenous living cells, there is every reason to conclude that they live here as they did in the leg by being bathed in lymph, as there seems to be no vascular blood-supply to the fascia in any part of the body.

Henschen has published the description of an operation somewhat similar to this in which he takes a large area of fascia, 18 by 21 cm., which he uses to cover the entire kidney, and sews it to the edge of the wound, putting the kidney in its normal upright position. I would say that the method offers none of the advantages of internal drainage secured by the oblique position of my operation, and, too, the wound in the leg is unnecessarily large, for that amount of fascia would hold a dozen kidneys in place. To me the oblique position is of the greatest importance; in fact, we cannot fully appreciate it until it has been demonstrated what sort of kidney can be saved with it that otherwise would have to be removed.

CONCLUSIONS

1. There are recurrences or non-relief after the usual nephropexy, according to Mr. Short of London, in as high as 40 per cent. of the cases; however, I am of the opinion that to know definitely the risk of recurrence much roentgenographic investigation must be made in these cases a year or more afterward.

2. The operation as here presented is not difficult or tedious; the securing of the fascia by the assistant does not increase the length of the operation; I feel that this method is advisable as it makes it practically impossible for prolapse of the kidney and urinary obstruction to recur.

3. This method makes it possible to place the kidney in either vertical or nearly transverse position, which cannot be done successfully by any of the usual methods or by the one recently proposed by Vogel, in which the capsule is used as a sling over the last rib, for the capsule is entirely too delicate to withstand any strain on it.

4. Any method which advises the passing of sutures of any sort into or through the parenchyma destroys more or less of the parenchyma by a fibrous degeneration and should not be used.

5. This method is indicated in all cases of nephropexy, and the transverse position is demanded in all cases of pyelitis, pyonephrosis and nephrolithiasis, even if the fascial strips should later slough out on account of the infection; for they would hold the kidney in the proper position until sufficient adhesions had formed.

6. The recurrence of kidney-stones is, I believe, due simply to the fact that the urinary obstruction is not removed, and I offer this operation with the idea of giving complete natural drainage of the urine.

Metropolitan Building.

ABSTRACT OF DISCUSSION

Dr. Walter E. Scott, Adel, Iowa: I believe that the kidney pelvis is, under ordinary circumstances, emptied by atmospheric pressure, and that under normal conditions, with the obstruction removed, the operation would be unnecessary. If the obstruction is not removed, however, then the operation would be of great benefit, because the atmospheric pressure would not be sufficient to empty the kidney pelvis.

Dr. Arthur L. Chute, Boston: I cannot agree with Dr. Scott. I think that we see peristalsis from time to time. We do not see it often, but I have seen it even in etherized patients. It seems to me that Dr. Fowler's operation assumes that gravity plays a tremendous part. I quite agree with what he says in regard to stasis as a factor in stone formation, but the operation is unnecessarily complicated. There is one other point: Dr. Fowler said he knew of no person having advised treatment to prevent the re-formation of stone. I think Albarran distinctly urged that, before you do these various plastic operations, you should do a nephrostomy and drain for a long time with that particular end in view

DR W M SPITZER, Denver· The muscular portion of the ureteral wall constitutes about three quarters of it, but the pelvis of the kidney, not having any muscular coat, according to Dr Fowler, he turns the kidney up so that it may drain mechanically Sections taken through the pelvis of the kidney, through the calices majores and even through the calices minores show that seven eighths of the walls of these structures are pure muscle, they do not, therefore, drain by gravity, but by muscular action, and do not, of course, have to be placed in the postion shown by him in order to drain

DR GRANVILLE MACGOWAN, Los Angeles Dr Fowler's operation contemplates the weaving of strong bands of fascial tissue through small loop holes in the capsule of the kidney itself, which necessitates the elevation from the kidney, at intervals, of strips of fascia of from one quarter to one half or three quarters of an inch in width and the weaving of these into a kind of piece work While I approve of it as a novelty, I doubt its efficiency Dr Fowler did not tell us exactly to what he attached the upper or lower bands of fascia that are to hold the kidney in its new place My experience would lead me to doubt that a kidney placed in the position described by Dr Fowler would stay put

Having operated on many kidneys and ureters for stones and strictures and kinks and various other things, I remember often finding these kinked ureters so intimately adherent to the organs surrounding them that it would be difficult to straighten up the kink without loosening up the ureter Further, I would imagine that it would sometimes require excision of a portion of the structures of the pelvis of the kidney to correct the kinking and narrowing of the ureter My criticism of the remarks of Dr Scott is that I do not see how atmospheric pressure could exercise much influence on a ureter that was bound down or a kidney that was out of place

DR W F BRAASCH, Rochester, Minn In a recent paper I reported over one thousand cases of pyelography in which I made a summary of some of the possible dangers and objections to that procedure In the first place, I do not think it advisable to do pyelography in any case in which a diagnosis can be made without its use In the majority of cases we can make the diagnosis without it In the second place, we ought to choose our cases carefully A highly nervous person should not be subjected to it If the patient has pain following such an examination, pyelography will be given the credit for it whether it caused the pain or not In the third place, we should not use pyelography in cases in which there is much residual urine in the renal pelvis, as with large hydronephrosis, because the collargol cannot escape, and pelvic contraction will force the collargol up into the straight tubules and cause abscess It is not necessary to use it in these cases, and diagnosis should be made easily with the catheter

Pyelography will not cause the patient any harm if, after choosing the cases, precautions are taken in its employment In the first place, the collargol should be carefully pulverized, should be used in not more than 10 per cent strength and should be carefully filtered It should not be injected, but should be allowed to run into the pelvis of the kidney by means of gravity It is impossible to inject it carefully No one knows the normal size of the pelvis of the kidney, it may vary from 1 to 25 c c The best way is to use the gravity method, by raising the collargol solution about a foot or two above the pelvis of the kidney and allowing it to run in slowly In that way colic never results, and there is always continued pressure at the time the roentgenogram is taken, which is a very important factor in the pyelography I believe that, if the precautions I have outlined are taken no harm will come This has been my experience in one thousand cases, certainly no permanent injury was done in any of them

DR G G SMITH, Boston· I should like to ask Dr Fowler what happens to the blood vessels when the kidney is tilted in this way. It occurs to me that the vein might be kinked, causing a congestion Of course, if he has had good results in all his cases, that would be against that assumption I wish that he would tell us how much the blood vessels have been in the way, and whether or not he has seen any evidence that this condition does occur

In regard to kinks in the ureter the ureter is a muscular tube similar to the intestines, but with a greater percentage of muscle in proportion to the lumen We find that kinks in the intestine are natural, but are overcome easily enough by the muscular contraction May it not be the same way in regard to kinks in the ureter, unless these kinks are definitely tied down by adhesions? If we get a kink in the bowel that is made fast by adhesions, we get obstruction One would think that the same thing would be true about kinks in the ureter May it not be true that a certain amount of kinking is natural and easily overcome by the ureteral peristalsis?

DR HUGH H YOUNG, Baltimore Dr Braasch's remarks in regard to the use of collargol have been timely We have had one or two cases recently that have disturbed us greatly One was in a man who had a troublesome kidney on one side We gave him a collargol injection very carefully, but following this he had colicky pains and great tenderness around the kidney Evidently there had been an extravasation of the collargol The renal function was almost suppressed, he became uremic, and we thought that he was going to die The gravity method and the weaker solutions are undoubtedly desirable

We ought to find a better material than collargol, which must be irritating, for the same irritation does not follow the use of water

Has Dr Fowler thought of trying to procure these fascial strips in an aseptic way at necropsy from persons dying from accident? It would be easy to keep them in an ice box in vaselin

DR O S FOWLER, Denver Dr Scott's inquiry has been answered by Dr MacGowan I should say that any method of nephropexy, or any other operation that gives as poor results as the ordinary nephropexy, ought to be abandoned If you will write to a hundred practitioners in this country about seventy five of them will say that they advise against nephropexy in cases in which the kidney is known to be the cause because the condition recurs We know that stone recurs, we know that pyelitis remains indefinitely and that it gives trouble for years and practically never subsides

In regard to the case Dr Spitzer spoke of I saw the patient first I found no tubercle bacilli at the time, but did find abscesses and large numbers of colon bacilli and much stinking pus Three weeks after this operation of nephropexy with fascial strips was done, the colon bacilli had disappeared and the urine was clear and could not be distinguished from normal urine Dr Spitzer and I, however, later demonstrated tubercle bacilli coming from that side, but the colon infection did clear up, and, so far as I know, remained so The same has been true of several cases of infection in which I made examination afterward and found the urine clear I am sure that this position of the kidney has helped the urine to escape from the kidney, not out of the pelvis necessarily, but so that the pelvis can get hold of it and expel it The muscular activity of the pelvis is slight

As to the method of attaching this fascia I bring the two loops together by plunging through the spinal muscles sufficiently low to give a sufficient amount of traction to rotate the upper pole inward and downward I push back the skin and bring the lower ones out at a point near the end of the twelfth rib or, I might say, above the rib You determine where to bring these two strips out by the position in which the kidney is to be placed

You can kink the blood vessels if you pull the kidney far out, but that is not necessary After you fasten the strips of fascia you can feel the blood vessels and see if the artery is pulsating properly

I think that Dr Smith is right when he says that if the kidney is properly brought up many of the kinks do not require straightening, but my idea for this operation was that I did two things brought the kidney up there and held it and at the same time, cleared up the adhesion or whatever it was that was causing the obstruction. If I were in a hurry to finish up the case I should let that go

The gravity method of using collargol is good. In my cases I have followed the method of finding the pelvic content at a previous sitting and then injecting half that amount. Lately I have injected 5 c.c. in all cases, and I have had no difficulty from that. I think, however, that the gravity method might be superior in keeping the ureter and pelvis distended properly.

The use of the fascia of cadavers, which Dr. Young has suggested, would be a good idea, but I believe that most patients would object to that procedure, and taking the fascia from the leg causes only a little pain following the operation.

Dr. MacGowan thought that the operation was elaborate. It is not elaborate. I have done the operation a number of times in thirty-five or forty minutes, and it takes that time to do an ordinary nephropexy; further than that, one does not know where the sutures are; the sutures are pulled through last, and often a suture is pulled out entirely. The weaving of the fascia in and out is not difficult.

THE PRACTICAL APPLICATION OF MILITARY FIRST AID IN RAILWAY SURGERY

LEON C. GARCIA, M.D.
Captain Medical Corps, U. S. Army
FORT MORGAN, ALA.

Oct. 19, 1913, in the afternoon, a special troop train bearing the officers and enlisted men of two companies of the Coast Artillery Corps, U. S. Army, and a detachment of the Hospital Corps, a total of 177, traveling at a rather high rate of speed, plunged through a trestle at Rube Burrows Creek, near Buckatanna, Miss., carrying three cars and the structure to the ground, about 35 feet below. The wooden cars and the trestle were more or less completely demolished, but fortunately did not take fire. Fifteen soldiers were instantly killed and two more, fatally injured, died within a few hours. Among the survivors there was not one who escaped injury; that is, the percentage of fatalities was 9.6 and the percentage of injured 100. Thus only a few of the injured were able to help in the work of rescuing their comrades from the wreckage or to assist in the administration of first aid.

The first step taken by the commanding officer was to organize rescue parties to remove all injured from the wreckage and have the hospital corps administer first aid (see illustration). The medical personnel available consisted of one sergeant and two privates first class hospital corps, U. S. Army, all of whom had been moderately injured. The detached-service chest and the hospital corps pouches had been buried in the wreckage, and it was some time before the detached-service chest was found. The first-aid packages were worn by all, and owing to their small size and compactness, were in good shape and readily available. Hemostats from an emergency case and first-aid dressings were used to control hemorrhage. In over ninety open wounds treated, many severe and accompanied with violent bleeding, there was not a single death, showing that the methods of controlling hemorrhage are thoroughly understood by the hospital corps men.

When the first relief train from Mobile, Ala., arrived, six and one-half hours after the wreck occurred, the following conditions governing the care of the injured had been met:

1. All hemorrhage had been controlled.
2. Wall tents sufficient to cover all severely injured had been put up.
3. All the injured had been dressed and bandaged, and the severely injured wrapped in blankets and placed on cots under canvas.
4. Stimulants had been administered to those needing them.
5. Analgesics had been used in every case in which it was necessary to control severe pain.
6. All lacerated, punctured, or incised wounds and all abrasions of the tissues had been painted with tincture of iodin.
7. All injured were ready for transportation.

The chief surgeon of the Mobile and Ohio Railroad, who arrived in charge of the first relief train, said that "the method adopted in handling the injured was remarkably efficient and satisfactory, and the application of first aid striking in its completeness." I was in charge of the transportation of the injured from the train to the civilian hospitals in Mobile, and to the post hospital at Fort Morgan, Ala., and their subsequent care at the post as soon as they could be transferred from the civil hospitals.

Wounded being given first aid and prepared for removal. White first aid bandages render injured conspicuous Iodized bandages, invisible as well as antiseptic, would be preferable

There are several interesting surgical points to note.

1. The efficiency of the first-aid packet, its ready availability over similar surgical supplies carried in bulk, and the thorough understanding of its use by the officers and enlisted men. Soldiers applying the first-aid dressing to each other's wounds were frequently heard to say: "Don't soil it with your hands after opening it," or to make similar remarks.

2. *The fact that in over ninety cases of open wounds there was only one infected.* This infection occurred in a case of compound fracture of the lower third of both

tibia and fibula in which the leg was pinned under the wreckage for six hours in such a position that an occlusive dressing could not be applied. This was also the only injury in which amputation was required.

3. A large number of severe lacerated wounds of the scalp were painted with tincture of iodin and stitched up. I subsequently washed dried blood, dirt, sand and cinders from the scalp and found in all cases a wound healing by primary union.

4. The cases of injury were classified as follows: Two injuries by incised wounds bisecting Stenson's duct; open wounds of every description; numerous contusions and sprains; a number of fractures of ribs; two fractures of femur; Pott's fracture; Colles' fracture; fracture of fibula; fracture of ulna; two fractures of clavicle; fracture of parietal bone; several cases of fracture of bones of foot; compound fracture of tibia and fibula; fracture of radius and dislocation of elbow; compound comminuted fracture of inferior maxilla; compound fracture of upper third of humerus with dislocation of the head which was protruding from the wound; numerous cases of concussion of brain or cord.

When it is considered that all these cases were primarily handled by the hospital corps men alone, that none were lost from hemorrhage, that only one case required subsequent amputation and *this the only one infected*, it shows the high efficiency of the hospital corps men in emergency work and the remarkable results obtained by the intelligent application of the first-aid dressing and the free use of tincture of iodin in open wounds of any character. The great loss of life in this wreck was due to crushing injuries with one rather remarkable exception, in which death was caused by a long sharp splinter of wood penetrating downward from the base of the neck into the arch of the aorta, the man becoming exsanguinated in a few minutes. The results of the application of the principle of military surgery to railway injuries are fully as gratifying as those obtained by their use in the treatment of gunshot wounds.

REPORT OF A CASE OF GRADUAL OCCLUSION OF THE COMMON CAROTID ARTERY IN THE TREATMENT OF PULSATING EXOPHTHALMOS

A. T. R. CUNNINGHAM, M.D., SPOKANE, WASH.

Many cases have been reported in which a pulsating exophthalmos has been dealt with by ligature of the common carotid or successive ligation of both carotids, but as the mortality of this operation is high, it would seem that a method of gradual occlusion of the artery would be preferable. The following report is of a recent operation in which a clamp[1] was used to accomplish this occlusion automatically.

History and Examination.—A. H., white, a delivery man, aged 39, had no previous disease, except a dysentery while in service in the Philippines. Four years ago last May, during a fight, he was struck a severe blow in the left cheek. He was considerably indisposed after the fight and that night spat blood continuously. On the second day afterward a roaring in his head began which gradually grew worse. At night it was so intense that he could not sleep lying down and spent most of the time sitting in a chair. This condition continued for two months after the injury, when he was seized with a sudden pain in the right temple and the eyeball protruded to a marked degree. There was some diplopia and the superficial veins over the eye and about the temple were dilated. He worked off and on, but because of the increase of symptoms while working was unable to remain steadily at his employment. In July, 1913, when returning home from work one evening, he had a seizure which rendered him temporarily unconscious. He was removed to the emergency hospital, where he was given treatment for sunstroke. Later he was taken to the Sacred Heart Hospital into the service of Dr. B. H. Roark. Dr. Roark and Dr. D. S. Brazeau made a diagnosis of pulsating exophthalmos and I was called to perform the operation of tying the common carotid artery. It seemed to be an ideal case for the employment of the gradual occlusion clamp, so Dr. M. M. Patton was asked to make a clamp for us, similar to the ones that he and Dr. Neff had used in their experiments.

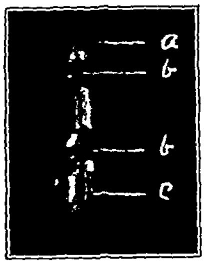

Fig. 1.—Neff's clamp after removal; *a*, hinge; *b*, rubber elastic; *c*, grooves in end of blades around which catgut was wound; catgut entirely absorbed.

Treatment.—The operation was performed by me, July 30, 1913, assisted by Dr. B. H. Roark, Dr. M. M. Patton and Dr. D. S. Brazeau. The right common carotid artery was exposed at the apex of the superior carotid triangle, and the clamp applied. Plain No. 2 catgut was wound around the exterior end of each blade, permitting compression of the artery, so that just a faint pulsation could be noticed distal to the clamp. The technic of adjusting the clamp was the same as that described by Dr. Neff in his article. A little difficulty was encountered from the fact that the ends of the clamp extended a little way beyond the artery so that it was necessary to suture a strip of the sternocleidomastoid muscle to the omohyoid muscle underneath the clamp, separating the carotid artery from the internal jugular vein and the vagus nerve. The incision was closed without drainage. After applying the clamp, the visible pulsation of the orbit disappeared and the bruit over the right side of the head was very much lessened. On the fourth day after the operation both the bruit and pulsation of the orbit had entirely disappeared, the patient declared himself free from the customary noise in his head and was able to sleep in a reclining posture without any trouble. He left the hospital on the tenth day and his symptoms seemed to have entirely subsided. An examination made September 30 showed that the exophthalmos was somewhat lessened, although the eyeball was still prominent, but there was no bruit and no visible pulsation of the orbit. The patient declared that the roaring in his head had entirely disappeared and he was doing some light work.

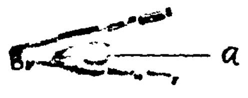

Fig. 2.—Clamp opened; *a*, segment of artery between the blades.

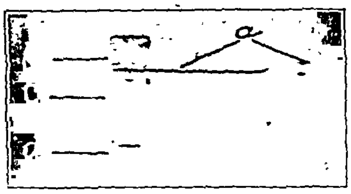

Fig. 3.—*a*, steel spring; *b*, German silver blades; *c*, groove for catgut; *d*, end of underlying blade turned up to prevent slipping of artery.

October 9 a second operation was performed and the clamp was removed. It had become encysted, and on account of its proximity to the trachea caused some annoyance during the act of swallowing. The encysted clamp could readily be felt in the tissues of the neck. An incision was made directly over the clamp through the fibrous capsule which had formed about it and which was lined with granulation tissue. The clamp (Fig. 1) had cut its way entirely through the artery and was easily lifted out of its capsule. No pulsation of the proximal end of the common carotid could be felt for some distance below the clamp. The severed end of the artery

---

[1] This clamp was similar to the one used by Dr. J. M. Neff in his experiments, as reported in THE JOURNAL A. M. A., Aug. 26, 1911, p. 700.

thinned out into the fibrous capsule which surrounded the clamp. No hemorrhage was encountered and the wound was closed in the ordinary manner. An examination of the clamp after its removal showed that the two blades were very nearly approximated, though between them was a thin layer of tissue. This layer proved to be a very much thinned-out and apparently clean-cut segment of the artery, its length corresponding to the width of the blades of the clamp. The walls of the vessel were easily separated, as shown in Figure 2.

Because of the tendency of the projecting ends of the original clamp to press on the adjacent structures of the neck, particularly the internal jugular vein and the trachea, which made it necessary to protect these structures from the clamp by suturing together the muscles underneath it, it was suggested that the clamp might be modified so that this objection would be overcome. With this in mind, I devised a clamp consisting of a steel spring to lie parallel to the artery, with two 28-gauge German silver blades to fit over the artery. The principle of application is the same as that in the Neff clamp, that is, the grooves in the end of the blades are to be wound with plain No. 2 catgut, but the compression in this clamp is secured by means of the spring instead of by rubber bands, as in the original clamp. The exact size of the clamp and its method of application are shown in Figure 3

From our experience with this case, we would conclude that the clamp automatically occluding the vessel is the ideal treatment for aneurysm and has a decided advantage over the immediate ligation of the vessel

---

CASE ILLUSTRATING VALUE OF ROENTGEN RAY IN DIAGNOSING OBSCURE FRACTURES

H. M. Stewart, M.D., Johnstown, Pa.

History.—A boy, aged 11, was referred by his family physician for a Roentgen examination with history of a fall from a swing, causing injury to elbow by direct force over the olecranon process.

Diagnosis.—Fracture of humerus at the base of the condyles as shown by Figure 1. Line of fracture somewhat longer behind than in front. Lower fragment drawn backward and upward by the action of the triceps, biceps and brachialis anticus muscles. Lower end of upper fragment projects in front of joint.

Treatment.—Fracture was thought to be reduced and put on an anterior angular splint before Figure 1 was taken. The case after examination was referred to a surgeon who under anesthesia reduced fracture and put on a straight splint, Allis' method, and Figure 2 was taken. It was found that slipping had occurred after reduction (which probably happened after putting on anterior angular splint) and it was decided to change to Jones' position. Figure 3 shows fracture reduced and dressed in acute flexion. Dressing was done in this position for four weeks, when gentle passive motion was begun. Figure 4 was taken three months later. It shows fragments in good apposition and line of fracture well united, which was further proved by perfect use of the arm.

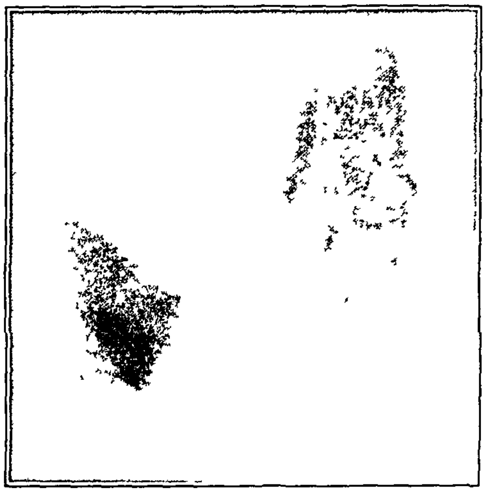

Fig 3.—Fracture reduced and dressed in Jones' position.

The history of the case illustrates that the general practitioner must realize the advantages of this method of diagnosis to his patient. The surgeon who neglects its use, neglects his interests and those of his patient. The best results can be

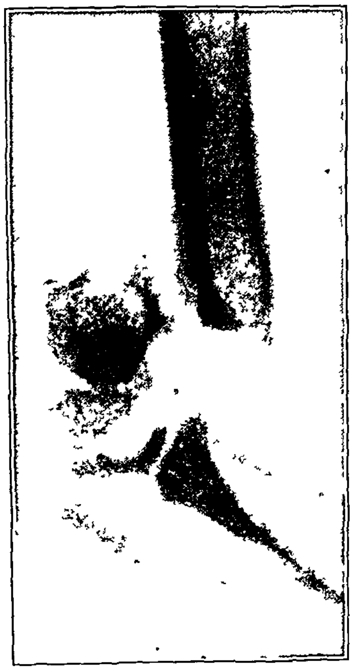

Fig 1 —Fracture of humerus above condyles thought to be reduced and dressed on anterior angular splint.

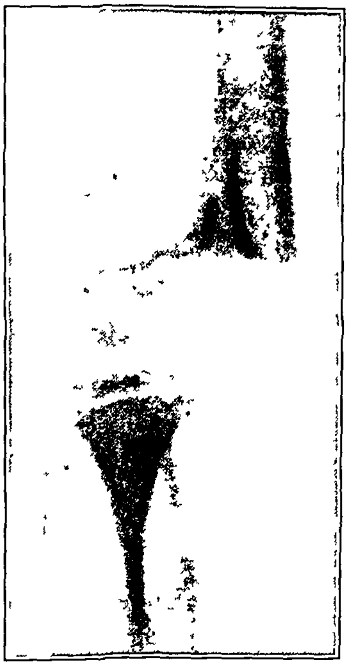

Fig 2 —Partially reduced under anesthesia and dressed on straight splint.

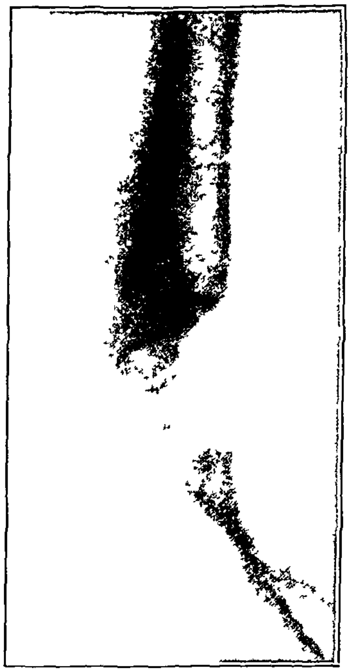

Fig 4 —Elbow three months later; perfect use of arm

obtained by making the roentgenogram before any attempt at reduction has been made as the knowledge gained prevents unnecessary trauma and manipulation, thereby greatly facilitating bony union and avoiding the danger of ununited fractures.

The practitioner must insist that a roentgenogram be taken in every case. This must be made and read by an experienced operator and is the evidence which must be preserved. A picture taken for diagnosis, together with a similar picture taken after the fracture is set, is the absolute evidence that his work has been properly done.

This case illustrates the accuracy in Roentgen diagnosis. The physician in every case to safeguard his and his patients' interests must insist on its employment. Thus with both protected, he can himself treat many more of his own patients and determine readily when operative intervention is necessary.

ABSCESS CAUSED BY FISH-BONE—HEMATEMESIS CONTROLLED BY HOT WATER

W. Hersey Thomas, M.D., Philadelphia

Assistant Professor of Surgery, Medico-Chirurgical College; Assistant Surgeon to the Medico-Chirurgical and Philadelphia General Hospitals

The cases about to be reported are from the surgical service of Dr. William L. Rodman, to whom I am indebted for the privilege of operating on and reporting them. Each is characterized by features which make it worthy of record. They occurred in the summer of 1912.

Case 1.—An abscess of the abdominal wall containing a fish-bone which had ulcerated through some portion of the gastro-intestinal tract, presumably the stomach.

History.—J. H., aged 45, a victim of chronic alcoholism, was admitted Sept. 17, 1912, with a mass in the abdominal wall just below the fundus of the gall-bladder. The liver was much enlarged but seemed to have no connection with the swelling. The mass was the size of a man's fist, evidently inflammatory and red, soft and fluctuating in the center. The notes of a prior admission six weeks earlier showed that the swelling was then present although it caused the patient no distress and showed no inflammatory action. The statements of the patient were unreliable but it seemingly had caused him great annoyance for several weeks prior to September 17.

Operation.—The case having been diagnosed as one of abscess of the abdominal wall, a vertical incision 3 inches in length was made over the swelling. After the escape of about 8 ounces of foul-smelling sanious pus, a slit-like opening 1 inch in length was discovered in the right rectus muscle, with hard, organized and almost cicatricial margins. The greater portion of the abscess cavity was beneath the rectus and a finger passed through the slit-like opening in this muscle discovered a long thin curved object (1/16 inch by 1⅞ inches) having the physical characteristics of a fish-bone. One end of the bone seemed to be loosely imbedded in the substance of the rectus and the free end pointed upward and to the left in the direction of the stomach. The peritoneal cavity was not opened on account of the danger of spreading the infection. The abscess cavity was gently scrubbed with gauze, well irrigated with hot normal saline solution, and packed with iodoform gauze.

Postoperative History.—The case passed out of my hands ten days later with the termination of the summer service. The bedside notes show an uneventful recovery. When seen one year after the operation the abdominal wall was in good condition and had caused him no trouble.

As no scar was present over the swelling prior to the operation, as the fish-bone was found beneath the rectus and as the greater portion of the abscess cavity was deeper than this muscle, the obvious conclusion was that the foreign body had ulcerated through from some portion of the gastro-intestinal tract.

I have just learned that a second fish-bone was removed from the left rectus by my colleague, Dr. W. P. Hearn, on Dec. 4, 1913. This was fifteen months after the first operation. The second fish-bone was surrounded by scar tissue and had recently caused the patient much discomfort.

Case 2.—Postoperative hematemesis following gastroplication and posterior gastrojejunostomy for a dilated and ptosed stomach, the hemorrhage being controlled by the direct application of hot water (130 F.) by means of a stomach-tube.

History.—R. B., a textile worker, aged 53, single, was admitted to the men's surgical ward of the Philadelphia General Hospital, July 27, 1912, complaining of sensations of painful weight and distress in the umbilical region soon after eating. He had had stomach trouble for more than thirty years. He did not use alcohol or tobacco. He gave a history of gonorrhea six years before, but none of lues. About a year before admission, he was jaundiced and at that time his stools were clay-colored. He was thin, nervous, and suffering from marked melancholia. His stomach was dilated, ptosed, and showed marked loss of motor power. Repeated analyses of the gastric contents were made. They usually gave a neutral or slightly acid reaction, contained no blood, no hydrochloric acid, showed a trace of lactic acid and had a total acidity which varied between 15 and 2. Oppler-Boas bacilli were absent. The red blood-corpuscles were usually about 4,000,000, the white blood-corpuscles 8,000; the hemoglobin percentage on admission was 80, but fell to 60 some weeks later. The urine was reported as containing nothing abnormal.

Operation.—When the abdomen was opened a markedly dilated and ptosed stomach was found, the greater curvature being two finger-breadths below the umbilicus and the lesser curvature displaced far below its normal position. As the gastrohepatic omentum was as thin as tissue-paper and the gastrophrenic and hepatoduodenal ligaments were not much more robust, shortening of these structures was impracticable; consequently a no-loop posterior gastrojejunostomy was performed and this procedure was followed by a plication of the anterior gastric wall from the cardia to within 2 inches of the pylorus. Six sutures of Pagenstecher linen thread were used for the gastroplication, the anterior gastric wall being thrown into folds parallel with the long axis of the stomach and the greater curvature drawn up as closely as possible to the lesser one. The length of the anastomotic opening between the stomach and jejunum was about 2 inches. During the entire operation the hemostasis was perfect and nothing occurred which could furnish a basis of explanation for the subsequent hematemesis.

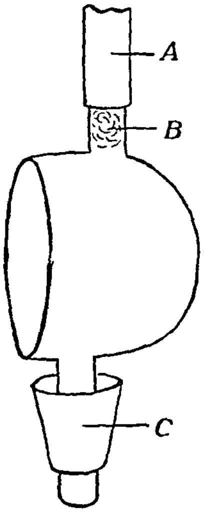
Hematemesis and Treatment.—When the patient was returned to the ward at 12:20 p. m. his temperature was 98.4 F., pulse 120 and respiration 20. At 1:30 p. m. the temperature was 98, pulse 104, respiration 20. At 2 p. m. he was asleep. At 3 p. m. he vomited 1 ounce of blood. At 3:30 p. m. he vomited 10 ounces of bright red blood; his pulse was still 120. He was then given an enema of 3 pints of normal saline solution at a temperature of 120 F. Soon after this he again vomited 10 ounces of bright red blood, the pulse rising to 128. At 5:15 p. m. he vomited 5 ounces of blood, his pulse remaining about the same as before. The saline enema was retained. At 6:15 p. m. the patient vomited 10 ounces of blood. At 6:35 p. m. a stomach-tube was passed and the stomach washed out with small quantities of normal saline solution at a temperature of 130 F. The funnel was held low, the fluid allowed to run in at any one time being small in amount to avoid a dilatation of the viscus. The washing was kept up until 4 quarts of the normal saline solution had been employed. There was no return of the hemorrhage. At 7:30 p. m. the patient was asleep. Pulse, 144. At 8:30 he was given hypodermoclysis (1 pint of normal saline with 1 dram of 1:1,000 solution of epinephrin). At 11:30 p. m. he had a hypodermic injection of atropin sulphate, 1/150 grain. After midnight he slept soundly most of the time but was disturbed occasionally by hiccup. During the next four days, he received enteroclysis twice daily (1 pint of normal saline). The subsequent recovery was uneventful and the patient was sent to the out-wards November 19. As the result of the operation the digestion was much improved and the distress after eating disappeared. The motor power of the stomach returned and the patient's color was markedly improved. His melancholia remained unchanged. The postoperative hematemesis in this case was severe, 36 ounces of practically pure blood being vomited during the first six hours after operation.

Hot rectal enemas (125 F.) for hematemesis were first advised by Tripier of Lyons in 1899, who considered the beneficial results obtained as analogous to those seen in epistaxis when the hands are plunged into hot water. To the best of my knowledge, the direct introduction of the hot water into the stomach for hematemesis was first employed with brilliant results by Dr. W. L. Rodman in 1902 in a case of hematemesis following posterior gastrojejunostomy when Tripier's and all other methods had failed. Since then Dr. Rodman has been equally fortunate with this procedure in a dozen cases of hemorrhage from the stomach from various causes. This case is an additional and striking example of the efficacy of this method.

A SIMPLE TECHNIC FOR BLOOD-CULTURES IN CHILDREN*

Jesse R. Gerstley, M.D., and Harry B. Fuller, M.D.
Chicago
Assistant in Pediatrics, Northwestern University Medical School, and Intern Sarah Morris Hospital for Children, Respectively

The difficulty of inserting a needle into the ulnar vein of a young infant has thwarted to considerable extent careful bacteriologic investigation of the blood during life. True, some work has been done. Jochman, Hektoen, Otten, Conradi, Spitta and many others report results, but in selected cases. Rotch and Low were successful in thirty-six out of forty-two attempts, but they found that in children under 4 years of age, in only 21 per cent. was it worth while even attempting. An important contribution is that of Churchhill and Clark, who made sixty-nine examinations in sixty-four cases; but these investigators also freely admit that to withdraw blood from a very young infant is often difficult if not impossible.



Apparatus for use in making blood-cultures in children: *A*, rubber tubing, to be used in suction by mouth; *B*, cotton; *C*, rubber cork to fit into test-tube of agar. The whole apparatus to be sterilized as it is after wrapping in gauze. This apparatus is practically identical with that used in the Finkelstein clinic, and described in this country by Blackfan, except that we found it more convenient to apply suction by mouth than by means of a pump.

To overcome this difficulty various modifications have been suggested. Delestre obtained from 1 to 2 c.c. of blood by incising the great toe. Rotch and Low mention Petruschky, who tried cupping, but give no reference and rule out his and Delestre's results on account of contamination. Slavyk took blood from the ear. Rotch and Low in some cases dissected out the ulnar vein under anesthesia. In the European clinics we have often seen the veins of the head used, usually the superficial temporal, with good results. Certainly the greatest improvement in our technic is that offered by Martha Wollstein and Edward Morgan. They wrap the patient in a sheet to secure the arms at the sides, lay him on a table with the head on one side and hyperextended, and during a paroxysm of crying when the external jugular is distended, use it as a source of their blood. They withdraw about 1 c.c. Their children varied in age from 10 days to 4 years. They made 100 cultures in eighty children, of which 32.5 per cent. were positive. In four of thirteen cases of lobar pneumonia, six of twenty-six cases of bronchopneumonia and nine of fourteen cases of empyema bacteriemia was shown. In their work, however, Wollstein and Morgan found some difficulty with fat, pasty-complexioned children and were unable to withdraw blood from their veins. Is it not possible to devise a technic to include these children also?

In Berlin, where the Wassermann test is done by the municipal laboratories, from 1 to 2 c.c. are required, and in the Finkelstein clinic this blood is obtained by means of a modified Bier's pump. It occurred to us that this method might also be used to solve some of these problems of obtaining blood. Through the courtesy of Dr. I. A. Abt we procured some specially made Bier's cups, and we wish to offer our results with these as a preliminary report. We must emphasize that we claim no originality in using the method of cupping to obtain blood, as this method has certainly been used for some time in the Finkelstein clinic and also has been reported from an American clinic by Blackfan; but so far as we know, no one has employed this idea for blood-culture work—doubtless fearing contamination. To overcome this objection one must develop a technic capable of giving sterile cultures from normal children—to be certain that the field is sterile. In all we have used twenty-four infants, all under 1 year of age, some only a few days. In our first few attempts the agar-plates were contaminated with a few colonies of staphylococci. A slight change in technic overcame this difficulty, however, and since then all our plates have been uniformly sterile.

The method is simple, requiring almost no preparation. The best point for the incision we found to be in the back between the vertebral column and the upper part of the scapula. It should be from 1 to 2 cm. in length and deep enough to enter the subcutaneous tissue. Sterilization of the skin is accomplished by first cleansing a considerable area with alcohol, then applying a wide area of tincture of iodin, allowing it to remain three minutes and reapplying. Lastly, one removes iodin from the skin over which the cup is to be placed by tooth-pick swabs and alcohol. The latter prevents any iodin entering the culture-medium.

The apparatus (see illustration) ready for use is wrapped in sterile gauze and sterilized with dry heat. Just as the incision is made an assistant unwraps the apparatus, fits it to a tube of melted agar cooled to 45 C. (113 F.), and it is applied. Slight suction for a minute or so will readily give 1 to 2 c.c. of blood. While the agar is being plated out, all superfluous iodin is removed from the skin to prevent blistering, and a gauze dressing applied. The wound heals in a few days. In a few cases we tried injection of Schleich solution, but this constricted the blood-vessels too much, and, strange to say, without its use, except for the immediate pain of the incision, the infants seemed to pay little attention to the procedure.

In conclusion we wish to state that we do not advocate this as a routine method. If it is possible to use the ulnar veins, they should be used. If the temporal veins are large, they should be used. By all means the external jugular should be tried, as recommended by Wollstein and Morgan; but if all these methods have been tried and found impossible, then we think that the technic which we have shown will probably solve the difficulty.

We wish to express our thanks to Dr. I. A. Abt, Dr. J. Hess, and Dr. E. Lackner for the use of their cases.

TENSION SUTURES

E. Viko, M.D., Salt Lake City

The aponeurosis and deep fascia are acknowledged to be the strongest structures of the abdominal walls. Therefore, after laparotomy, secure and close apposition of the cut edges of these structures is made in order to prevent postoperative hernia.

For the purpose of relieving the usual continuous absorbable, aponeurotic suture from violent strains, such as from coughing, vomiting, etc., tension or reenforcing sutures are employed. These are figure-of-eight or through-and-through sutures taking in the aponeurosis, subcutaneous tissue and the skin.

---

* From the Sarah Morris Children's Hospital; read before the Chicago Pediatric Society, Oct. 28, 1913.

If the continuous aponeurotic or deep fascia-suture could be put on the slack or relieved from all strain and to merely act as an apposition suture, this would secure an ideal condition for wound healing. The figure-of-eight or through-and-through sutures fall short of this ideal, as they take in a very limited area and act mainly as reenforcing sutures at the spot where inserted.

For some time I have been using with great satisfaction and a sense of security what might be called crossed mattress-sutures. They take in a large area of the aponeurosis, and taking the stain off from the continuous suture, act as true tension sutures.

Another desirable action of this suture is: As it firmly holds together the cut edges of the subcutaneous tissue and skin during healing, no ugly, broad scar results, but only a faint streak.

It is quickly placed as follows: Penetrate skin and subcutaneous tissue at *a* in illustration, emerge in front of aponeurosis at *b*, cross over in front of suture line and penetrate aponeurosis at *c*, emerge at *d*, cross over in front of suture line and penetrate subcutaneous tissue at *e*, emerge through skin at *f*. The opposite suture is placed in a similar manner. Two or three pairs are used. After the subcuticular or continuous horsehair suture is taken, the crossed mattress-sutures are tied over rolls of gauze. They are readily removed by cutting one limb of each suture close to the skin.

THE PREPARATION OF DRIED "ZYMASE" FROM YEAST, FOR USE IN FERMENTATION TESTS OF URINE *

Jacob Rosenbloom, M.D., Ph.D., Pittsburgh, Pa.

On account of the well-known fact that, by fermentation with yeast, glucose is decomposed into alcohol and carbon dioxid, we have at present the excellent fermentation test for glucose. This method is not only valuable for qualitative purposes to distinguish the kind of reducing substance present in the urine but is of great use for the quantitative estimation of glucose.

The method has one disadvantage from the necessity of using perfectly fresh yeast in its performance. I have, however, devised a method to isolate the enzyme from the yeast in a dried condition and have found that the enzyme in this state is still active five months[1] after its preparation.

Grind up thoroughly in a mortar three cakes of compressed yeast with about 200 c.c. of water and 10 gm. of sand. Press this fluid through cheese-cloth and add the expressed liquid, with constant stirring, to about five times' its volume of 95 per cent. alcohol. Allow the precipitate to settle, filter and wash the precipitate on the filter-paper with about 50 c.c. of alcohol followed by 50 c.c. of ether. Allow the precipitate to dry in the air after spreading it on a glass plate. Powder and put residue in a tightly corked *amber* bottle. To use this powder to ferment urine, take about as much as the end of a medium-sized knife blade will hold, mix it thoroughly with the urine to be tested and pour the mixture into a fermentation tube.

I have found that certain well-known conditions are not observed by many workers when using the fermentation test, so it may be of some service to call attention to these details.

1. The urine to be tested, freed from protein if found present, must previously be slightly acidulated with 1 per cent. tartaric or acetic acid solution. This lessens the possibility of bacterial fermentation; also some of the carbon dioxid of the urine may have chemically combined with the monohydrogen sodium phosphate that is present, forming dihydrogen sodium phosphate and sodium bicarbonate. This source of possible error is avoided by the acidulation which converts the monohydrogen salt into the dihydrogen salt.
2. The urine should be boiled after acidulating to dislodge any combined carbon dioxid.
3. Besides the fermentation test applied to the urine, two control tests should be made, the one with normal urine to which a little glucose is added to prove the activity of the yeast, and another of normal urine alone, to prove by the absence of gas, that there is no self-fermentation of the yeast. With these points in mind it will be found that the fermentation test can always be relied on and will not be found wanting.

5659 Beacon Street.

Therapeutics

PROTEIN POISONING—ANAPHYLAXIS—URTICARIA

PROTEIN POISONING

The fact that bacteria could cause protein poisoning was first noted and the condition described, in 1903, by Victor C. Vaughan of Ann Arbor. Protein poisoning is the cause of most urticarial conditions, of many of the skin eruptions, of many of the simple, so-called *febricula* (a name applied to a fever lasting one or two days with no positive diagnosis determinable), and all of these disturbances are really forms of anaphylaxis.

Some protein poisons may cause a lowered or subnormal temperature rather than fever. This is apparently due to a marked dilatation of the peripheral blood-vessels, especially of the splanchnic area, similar to that in shock. With other protein poisonings there may be, for several days, an irregular temperature with morning remissions. If such poisonings persist and the toxins are not rapidly expelled, neutralized or destroyed, there will be an increased elimination of nitrogen and a progressive loss of weight.

A scientific discussion of these protein poisonings has recently been presented by Vaughan,[1] and should be read by every physician, as a thorough understanding of the causes of these disturbances of the blood and nervous system will lead to proper treatment.

The symptoms of many diseases are due to the so-called "parenteral" digestion of proteins. Hay-fever and paroxysms of asthma are caused in sensitive individuals by the pollen of different plants, the emanations from different animals, or the dust or odors of many kinds of substances. Any susceptible individual may be sensitized, so to speak, by one or more of these irritant causes and not by others. The inhalation of some substances in almost intangible amounts may cause serious inflammation of the upper air-passages and even of the bronchial tubes.

---

* From the Biochemical Laboratory of the Western Pennsylvania Hospital, Pittsburgh, Pa.

[1] It is possible that I shall find that this preparation will be active for a much longer time, but as five months have passed since its preparation I think the value of this method has been demonstrated.

[1] Vaughan, Victor C.: The Protein Poison and Its Relation to Disease, The Journal A. M. A., Nov. 15, 1913, p. 1761.

Many drugs taken internally may sensitize individuals who have peculiar idiosyncrasies against them, and may cause, primarily, gastric and duodenal irritation, and secondarily, disturbances similar to protein poisoning (such as urticaria and swelling of the mucous membranes), which may become serious, as occasionally seen with quinin, salicylates, antipyrin and other coal-tar products. Many of the so-called genito-urinary stimulants of the copaiba class may cause considerable irritation and eruption of the skin.

Living bacterial cells, like other living cells, must form ferments to prepare their food for absorption. Consequently, as described by Vaughan, for a given bacteria to be poisonous to the human animal, for instance, it must have the ability to split up and feed on the proteins of the human being; otherwise bacteria cannot grow and cannot harm the host. Another prerequisite to such poisonings is that the ferments in man must not be immediately destructive to the invading bacterium, although ultimately antibodies may be formed in sufficient amounts to destroy it. A bacterium, then, able to digest the proteins in man renders this host susceptible to its poisoning, unless he has been previously protected either by a previous infection from the specific bacterium or by a previous inoculation or vaccination with the germ or its products which so promotes the formation of antibodies or antiferments that it renders the individual immune. This is the scientific basis of vaccination and protective inoculation.

The value of autogenous vaccine treatment, or, at times, stock vaccine treatments of local infections, is due to the fact that the general system is not producing ferments sufficient to eradicate the special bacterium and its poison, and the inoculation so stimulates the general production of antibodies or ferments, that the local disease is stopped and later eradicated. On the other hand, if a person is suffering from a general poisoning or infection, such vaccines are of doubtful value or may be actually harmful by overstimulating the already worn-out antagonistic cells, and the individual is thus really injured by such vaccination. Therefore the frequent and careless use of vaccines is deplorable and often inexcusable.

ANAPHYLAXIS

To be closely associated in discussion with protein poisoning, urticaria and the conditions that have as a symptom an eruption of the skin, is the condition of hypersensitiveness termed anaphylaxis. If proteins are naturally digested in the stomach and intestines and are absorbed only as the molecular forms that normally reach the blood, no sensitizing or anaphylaxis or intoxication will occur. If, however, the proteins are absorbed before they reach their final disintegration stages and are then digested parenterally, that is, outside of the intestine, or if they reach the blood through other channels or are injected directly into the tissues, such poisoning or "reaction" occurs, attended by more or less fever, nervous irritability, increase in the number of the white corpuscles, changes in the blood-plasma, kidney irritation, and frequently diarrhea. The system, however, soon produces active or immune bodies to combat the specific ferment.

The length of time before the occurrence of hypersensitiveness or sensitization varies; the poisoning may be acute, as in so-called "ptomaine poisoning" or in that which occurs from some such toxin as is found in toadstools; or it may require a number of days for the person affected to be sensitized. Sensitization from a serum injection or from the absorption of some protein irritant may not happen until after a series of days, perhaps a week, and this sensitization will often not be recognized until a second injection (the intoxicating dose) of the same serum is administered, or until more of the same protein poison is absorbed, when reaction becomes evident and is sometimes serious in its outcome. Therefore, it cannot be too carefully noted that injection of prophylactic or antitoxic serums should ordinarily not be repeated too long after the first injection has been given. This is not always true of all antitoxins or all bacterins, but it is more or less constantly in evidence. Sometimes the system becomes tolerant to this irritant, and a larger dose, given to obtain a desired reaction, will be borne. In other instances the patient becomes hypersensitive, and the repetition of a previously harmless dose may cause an intense reaction. This has occurred with diphtheria antitoxin a number of times, and would occur with any horse-serum in patients who are susceptible to, and are always hypersensitized by, emanations or dust from horses.

Persons peculiarly susceptible to horse-serum may develop bronchial edema and die of suffocation within a few minutes or hours after an injection of diphtheria antitoxin; or, in certain instances, they may not develop the asthma, urticaria, joint-pains and fever until after a series of days. Such late symptoms are not generally dangerous, although albumin may appear in the urine, but generally the kidneys rapidly recover and all the symptoms disappear. Other persons may have an intense local reaction to an injection of antitoxin or vaccine out of all proportion to the injury caused and later may show some of the general symptoms. Such cases are very troublesome and more or less serious, but rarely cause death.

When antitoxin is indicated in diphtheria, or horse-serum in hemorrhage, one should be sure to inquire whether or not the patient is an asthmatic or a sufferer from hay-fever, and especially if horse emanations cause either of these conditions. If such is the case, all horse-serums are positively contra-indicated. Even severe diphtheria must be combated without the aid of antitoxin, as its use may cause the death of such patients.

This reaction of the blood, that is, anaphylaxis, to different poisons, seems to be the cause not only of the symptoms which follow vaccination against small-pox, typhoid fever and other diseases or infections, but also of the symptoms of hay-fever induced by different pollens, varieties of dust or odors. It is the cause of asthma in many persons; of the urticaria produced in susceptible individuals by shell-fish, buckwheat or strawberries, and of the symptoms of sensitization or anaphylaxis which sometimes occur even from such ordinary foods as veal, pork, eggs, some kind of cheese and milk.

It seems also, with our greater knowledge of this blood disturbance, that quite probably the skin eruptions of the exanthems, of typhoid fever, and even of primary syphilis may be due to this hypersensitizing of the blood by the proteins of the specific bacteria. Our recognition of the anaphylactic temperature caused by serums and toxins suggests that the fever process of the various infections may also be due to the protein poisoning caused by the germ of infection.

Discussion of the treatment of these specific infections would lead us astray, but the symptoms attributed to the poisoning protein in the blood are more or less the same, namely, fever, irritation of the central nervous system, cutaneous irritability and perhaps eruption, more or less muscle pains and concentration of the urine with kidney irritation, lumbar backache, and either constipation or a diarrhea that shows bowel irritation without complete evacuation. In some instances vomiting is present, especially in children, and headache is frequent or constant, dependent on whether the absorption of the poison is intermittent or continuous.

Whatever the infection or irritant that causes these symptoms may be, the general treatment is the same, namely, whatever of the poison is still in the intestine should, if possible, be removed by a free, non-irritating catharsis by castor oil, calomel, or a saline, as advisable. It is quite possible that more of certain kinds of intestinal poisons may be absorbed under the influence of an oil than would be if a saline is administered. If it is a poison to which the patient is susceptible, he certainly should receive no more of the irritating food. If the disturbance is due to the proteins of some specific germ, he should receive only such nutriment as is easily digested, and therefore less likely to furnish incompletely disintegrated protein products for absorption, thus to add more irritants to the already disturbed blood. Consequently, individual idiosyncrasies should be learned and the signs of indigestion noted; the foods that probably will digest most readily and are not too rich in proteins are the only ones that the patient should be allowed.

The next object is to dilute the poison already in the blood by the administration of large amounts of water, perhaps medicated, acidulated, alkalized, carbonated or plain, as seems indicated. The greater the amount of urine passed, and the freer the perspiration, the sooner, in all probability, will the toxins be eliminated, unless they are produced in overwhelming quantities.

If there is an antitoxin for the condition, it should, of course, be administered. The skin should be frequently soothed with warm water(often best made alkaline with sodium bicarbonate) sponging and then perhaps powdered with a simple bland powder, such as starch. An irritated, erupted skin should not be freely sponged with pure alcohol, which dries the skin and will cause more irritation. The more moisture there is in a skin with an urticarial or exanthematous eruption, the less is the irritation and itching. The temperature is also more rapidly reduced by evaporation. If the fever is excessively high and must be reduced, of course the usual hydrotherapeutic measures should be inaugurated.

CALCIUM

The nutritional value of calcium and its necessary participation in many functions of the body have been recently described.[2] The relationship of diminished calcium content of the blood to some angioneurotic edemas and to some of the urticaria-like localized swellings and edemas, has been lately shown by investigators. It seems to be a clinical fact in many cases that these exudates and symptoms of anaphylaxis are prevented, or are quickly improved, by the administration of calcium. Experimental evidence as to the value of calcium in preventing anaphylaxis is rather contradictory.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLE HAS BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. ITS ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES."

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN, IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

ELARSON.—Strontium Chlorarsenobehenate.—Elarson is the strontium salt of chlorarsenobehenolic acid, containing about 13 per cent. of elementary arsenic and about 6 per cent. of chlorine.

Action and Uses.—Elarson has the action of arsenic but the arsenic being in lipoid-like combination is said to be much better utilized in the system and to exert its therapeutic effects in smaller doses than other organic arsenical preparations. It also possesses the advantage of being relatively free from irritating action on the gastro-intestinal tract.

Elarson has been employed with excellent effect in anemias due to various causes, such as chlorosis, and seems to be beneficial in diseases of the skin, phthisis, malignant disease, chorea, neuralgias, etc. By its action in improving the condition of the blood it appears to exert a beneficial influence in some cases of epilepsy.

Dosage.—The average adult dose of elarson is 0.008 gm. (1/8 grain), three to five times daily, best taken about an hour after meals. Elarson is marketed in the form of tablets only. (See below.)

Manufactured by the Farbenfabriken vorm. Friedr. Bayer & Co., Leverkusen, Germany (The Bayer Company, Inc., New York). U. S. patent applied for. U. S. trademark No. 91419.

Elarson Tablets.—Each tablet contains elarson equivalent to arsenic 0.0005 Gm. (1/128 grain).

Elarson is prepared by treating behenolic acid with arsenic trichloride and converting the oily acid thus formed to the solid strontium salt.

Elarson is an almost white, amorphous, tasteless powder, insoluble in water and but slightly soluble in alcohol and ether.

On heating it decomposes with evolution of volatile organic substances and elementary arsenic, frothing and turning black.

If elarson is shaken with water (1:20) the filtrate should not change litmus, become turbid on addition of silver nitrate or barium chloride solution nor leave a residue on evaporation.

If 2.0 Gm. of elarson be boiled with 25 Cc. of a 15 per cent. alcoholic solution of potassium hydroxide for about one-half hour, using a reflux condenser, and if to a portion of the alcoholic fluid, which has been diluted with water, diluted sulphuric acid is added and then filtered, half of the filtrate saturated with hydrogen sulphide, should yield a voluminous yellow precipitate of arsenic sulphide. If to the other half of the filtrate nitric acid and silver nitrate solution be added a precipitate of silver chloride should be formed. If the second portion of the alcoholic solution be diluted with water, acidified with dilute hydrochloric acid and filtered, the filtrate should yield a precipitate of strontium oxalate on addition of ammonium hydroxide and ammonium oxalate solutions.

Medical Education.—A debt of gratitude and unstinted praise is due the Council on Medical Education of the A. M. A. for their exhaustive analysis of medical education in this country, and to the Carnegie Foundation for the Advancement of Teaching for the study of medical education in England, Germany and France. The results of these investigations will have a pronounced influence on the further development of medical teaching in this country. The normal influence of an education that is obtained in an atmosphere that abounds in honest endeavor, conscientious appreciation of the needs of the student and a high conception of medical ideals cannot but leave its indelible impress, to accompany the physician long after he has wandered afar, beyond the guidance and control of his early mentors.—Arthur J. Patek, M.D., *Wisconsin Med. Jour.*

AVAILABILITY OF NUTRIENTS FROM PLANT SOURCES

[illegible] attempting to debate the question of the [illegible] and disadvantages alleged to accrue from the [illegible] foods of animal and vegetable origin, respectively, we are bound to admit, when we analyze the problem of nutrition, that man and animal alike are dependent on plants for a suitable store of nutrients. As a recent writer has expressed the situation: man is at present still a parasite living on the plant kingdom. The final source of human energy is found in plants. In so far as mankind obtains energy by consuming the flesh of the domestic animals, only a fraction of the supply taken by the latter in the plant products which they ingest can ever reach the sphere of usefulness to man. The animals which furnish food to man function as expensive converters of the energy of plants into a form directly available for his uses. Only a very small residue of the total energy-intake of such animals is left in the tissues which they furnish as nutrients to man; the great bulk of what has been consumed has become lost in the processes of animal life during the long periods of growth and maintenance necessary before the animal food-products can be marketed. To appreciate this, one need only consider for a moment what relatively enormous intakes of energy it requires to secure a final few thousand calories in the form of the flesh of cattle for human consumption. A cow eats a liberal plant ration daily during several years before the nutrient products which she furnishes are ready for the market.

It is evident from the foregoing that, considered solely from the standpoint of economy, it would represent a decided advantage if man could utilize more directly the energy which he now commonly secures only after it has been converted by animals, with great incidental losses, into the forms that suit his present preferences, if not his absolute physiologic needs. Our vegetarian friends will at once remind us that it has repeatedly been found quite compatible with health and happiness to provide for human nutritive needs directly and entirely from the plant kingdom. Despite this fact, which must readily be admitted, it is undoubtedly true that the domestic animals still are provided from the plant world with various foods of which man is at present unable to avail himself.

Hitherto the contributions of the vegetable kingdom to the dietary of human beings have consisted essentially of those parts of plants which serve as storage depots—as reserve supplies for subsequent growth. Seeds, roots, tubers and fruits represent the chief types of plant products which find their way into the ration of mankind. These are by no means all well adapted for direct food-service in the human alimentary apparatus; but the progress of science and the industries and the ingenuity of the domestic arts have little by little so improved the form in which such materials as cereals, nuts, etc., are presented for human consumption, that their utilization has become greatly enhanced. Processes for grinding and comminution, the almost indispensable precautions of cooking and baking—all of which we rarely stop to consider as innovations of human ingenuity—are not natural operations; on the contrary, they have been evolved by the genius of man so that he might readily take direct advantage of the energy which, in the cruder forms in which Nature has stored it, some animals are better equipped to utilize. The inherent indigestibility of "raw" starch, as exemplified by the potato, is overcome by cooking; the further comparative resistance of cereal grains to permeation by digestive juices is minimized by milling and subsequent disintegration by cooking. The history of the struggle to wrest energy from the native plant-products without the expensive necessity of calling on the herbivorous animal to act as an intermediator in the process, has been a long one.

There are, however, still other forms of plant structures of which the herbivora make use freely in nutrition, but which mankind has not yet employed with signal success in so far as extracting energy freely from them is concerned. The green parts of plants, rich in such protoplasmic constituents as protein and nuclear material, present the nutrients so completely enclosed in walls of cellulose that they can be utilized only to a small degree and with enormous alimentary waste. We may soften them by cooking and comminute them by mastication, without liberating their foodstuffs to any adequate extent. Man lacks a cellulose-dissolving digestive agent; and hence he cannot depend on the fermentative processes which, in the large cecal reservoirs of herbivorous animals, facilitate the dissolution of the cell-walls of the green fodders.

Friedenthal,[1] in particular, has cherished the belief that it may be possible to accomplish for the so-called green vegetables, rich in plant protoplasm, a sort of comminution which would disintegrate the resistant cell-walls and impermeable structures and render the contents more available for digestion and assimilation by man. The technic of such manipulations, in the case of products like spinach or lettuce or string-beans or any of the large list of green vegetables, involves desiccation and is by no means as easy as might appear at first consideration; for the degree of subdivision called for is both minute and complete, if success is to be attained.

---

[1] Friedenthal, H.: Ueber die körperliche Anpassung des Menschen an die Ausnutzung pflanzlicher Nahrung, Vortrag in der physiologischen Gesellschaft in Berlin, Med. Klin., 1912, No. 5; Die Anpassung des Menschen an die Ausnutzung pflanzlicher Nahrung, Arch. f. d. ges. Physiol., 1912, cxliv, 152.

Professor von Bergmann and Dr. F. W. Strauch[2] of the Municipal Hospital in Altona have tested the validity of Friedenthal's scheme by studying the utilization of plant products prepared in the form of impalpable powders by his process. The outcome has been decidedly gratifying and will, we believe, pave the way for useful innovations in the use of vegetable foods. For example, Strauch found the utilization of bean powder fed to men in the form of a purée, far greater than is true of string-beans served in the usual form. Spinach, carrots, cabbage, etc., similarly prepared, were enjoyed with singular freedom from the troublesome intestinal symptoms which so often follow their use. In such gastric and intestinal diseases as ulcer, colitis and typhoid, in which these "fresh vegetables" are often excluded from the dietary, the comminuted-powder products were employed with impunity and to advantage. The usefulness of these familiar plant-products, so often classed as offenders against the alimentary comfort of those who ingest them, appears to have been augmented by successful innovation in their preliminary treatment. A group of vegetable products has thus been converted from a mechanical agent, serving largely as so-called roughage, into a not unworthy source of nutriment. The efficiency here recorded is rendered the more striking by the report from the Altona clinic that 300 gm. (10 ounces) per day of vegetable powder, equivalent to 3 kg. (6 pounds) of the fresh plant, may easily be assimilated—an amount which in the natural state could not be tolerated. It is not too much to assume that possibly by similar suitable preparation, such plant products as the grasses, which have hitherto been excluded from the dietary of man, may yet be used as direct sources of energy in human nutrition.

OLD-TIME MEDICAL HUMOR

It has been said that there are altogether only twenty-nine jokes in the world, and that most of these can be found in the specimens of Roman humor which have been preserved for us by the satirists and wits of the classical and postclassical periods. How far this may be true is a question, but an excellent illustration of it is afforded by Dr. Raymond Crawfurd's recent article on "Martial and Medicine."[3] Martial was the acutely observant satirist and critic of a city that in the course of a little more than a century had risen in population from less than a hundred thousand to nearly two million. Into that city the wealth of the world was being poured, and to it came men of all nations seeking to get into the center of things; and his epigrams come home to us with greater force from the fact that many of us live under circumstances much resembling those in which Martial lived and wrote. Some of the oldest jokes known to medicine and dentistry are found in these satires. Pathologic conditions that are usually thought of as having been much more recently noted were humorously and satirically touched on by Martial nearly two thousand years ago. All of the references are distinctly modern in flavor, and as this is the time of social reunions and banquets which physicians must often attend and at which they sometimes make addresses, a few of these old jokes may be useful.

The old saying, "The surgeon buries his mistakes," which probably first arose through medical jealousy, has its exemplification in Martial's pun on the surgeon turned undertaker.

> Diaulus undertook of late
> The operator's art,
> But now prefers to operate
> The undertaker's part.

The fact that there was clinical teaching and that patients complained of abuses in it is shown by one of Martial's epigrams. The lines contain history and a warning that the patient's feelings must be considered if the really great good that should be secured from clinical teaching is to be obtained.

> I lay ill; but soon Symmachus sought me
> With a class of a hundred young men
> Whose hundred cold paws have brought me
> The fever I lacked till then.

Martial ridicules the false adornments worn by the women of his time. He originated the quip that "they lie who say that Phoebe dyes her hair black—she buys it black." His couplet on the teeth belongs in this class.

> Laecania has white teeth, Thais brown.
> How comes it? One has false teeth, one her own.

Unfortunately, there were no means of replacing the eyes lost through the many eye diseases of Martial's time. Ambroise Paré, in the sixteenth century, was the first to make a regular use of false eyes. Martial says of one of the fair ladies of Rome:

> False teeth and hair flaunts Laelia shamelessly
> But not false eyes, for these she cannot buy.

Crawfurd quotes epigrams from Martial concerning two affections that are of special interest at present. While the poet pokes fun at the oculists and indeed seems to have a little grudge against specialists, he pictures one of them as warning his patient that if he

Professor von Bergmann and Dr. F. W. Strauch[2] of the Municipal Hospital in Altona have tested the validity of Friedenthal's scheme by studying the utilization of plant products prepared in the form of impalpable powders by his process. The outcome has been decidedly gratifying and will, we believe, pave the way for useful innovations in the use of vegetable foods. For example, Strauch found the utilization of bean powder fed to men in the form of a purée, far greater than is true of string-beans served in the usual form. Spinach, carrots, cabbage, etc., similarly prepared, were enjoyed with singular freedom from the troublesome intestinal symptoms which so often follow their use. In such gastric and intestinal diseases as ulcer, colitis and typhoid, in which these "fresh vegetables" are often excluded from the dietary, the comminuted-powder products were employed with impunity and to advantage. The usefulness of these familiar plant-products, so often classed as offenders against the alimentary comfort of those who ingest them, appears to have been augmented by successful innovation in their preliminary treatment. A group of vegetable products has thus been converted from a mechanical agent, serving largely as so-called roughage, into a not unworthy source of nutriment. The efficiency here recorded is rendered the more striking by the report from the Altona clinic that 300 gm. (10 ounces) per day of vegetable powder, equivalent to 3 kg. (6 pounds) of the fresh plant, may easily be assimilated—an amount which in the natural state could not be tolerated. It is not too much to assume that possibly by similar suitable preparation, such plant products as the grasses, which have hitherto been excluded from the dietary of man, may yet be used as direct sources of energy in human nutrition.

OLD-TIME MEDICAL HUMOR

It has been said that there are altogether only twenty-nine jokes in the world, and that most of these can be found in the specimens of Roman humor which have been preserved for us by the satirists and wits of the classical and postclassical periods. How far this may be true is a question, but an excellent illustration of it is afforded by Dr. Raymond Crawfurd's recent article on "Martial and Medicine."[3] Martial was the acutely observant satirist and critic of a city that in the course of a little more than a century had risen in population from less than a hundred thousand to nearly two million. Into that city the wealth of the world was being poured, and to it came men of all nations seeking to get into the center of things; and his epigrams come home to us with greater force from the fact that many of us live under circumstances much resembling those in which Martial lived and wrote. Some of the oldest jokes known to medicine and dentistry are found in these satires. Pathologic conditions that are usually thought of as having been much more recently noted were humorously and satirically touched on by Martial nearly two thousand years ago. All of the references are distinctly modern in flavor, and as this is the time of social reunions and banquets which physicians must often attend and at which they sometimes make addresses, a few of these old jokes may be useful.

The old saying, "The surgeon buries his mistakes," which probably first arose through medical jealousy, has its exemplification in Martial's pun on the surgeon turned undertaker.

> Diaulus undertook of late
>   The operator's art,
> But now prefers to operate
>   The undertaker's part.

The fact that there was clinical teaching and that patients complained of abuses in it is shown by one of Martial's epigrams. The lines contain history and a warning that the patient's feelings must be considered if the really great good that should be secured from clinical teaching is to be obtained.

> I lay ill; but soon Symmachus sought me
>   With a class of a hundred young men
> Whose hundred cold paws have brought me
>   The fever I lacked till then.

Martial ridicules the false adornments worn by the women of his time. He originated the quip that "they lie who say that Phoebe dyes her hair black—she buys it black." His couplet on the teeth belongs in this class.

> Laecania has white teeth, Thais brown.
> How comes it? One has false teeth, one her own.

Unfortunately, there were no means of replacing the eyes lost through the many eye diseases of Martial's time. Ambroise Paré, in the sixteenth century, was the first to make a regular use of false eyes. Martial says of one of the fair ladies of Rome:

> False teeth and hair flaunts Laelia shamelessly
> But not false eyes, for these she cannot buy.

Crawfurd quotes epigrams from Martial concerning two affections that are of special interest at present. While the poet pokes fun at the oculists and indeed seems to have a little grudge against specialists, he pictures one of them as warning his patient that if he continues to indulge in liberal potations he will surely lose his sight, as dimness of vision has already begun. The craving is too strong for the patient and his sight is lost. Dr. Crawfurd has suggested that the verses should be labeled "Albuminuric Retinitis."

[3] Crawfurd, Raymond: Martial and Medicine, Lancet, London, Dec. 6, 1913, p. 1643.

Aulus, there's Phryx, that fine old winebibber
Blind of one eye and of the other blear:
His doctor Heras said, "Drop alcohol
For if you take it, you'll not see at all."
Laughing, Phryx wished his eyes a last good-bye
And ordered cups to be mixed frequently:
D'you want to know the consequences? Why,
'Twas wine to Phryx, but poison to his eye.

Martial seems to suggest that chronic constipation played a large part in the illnesses of Rome and that it could be told from the appearance of a man that he was suffering from this disorder. The ordinary remedies included lettuces, mallows and other vegetables having a large residue. The use of prunes was evidently a favorite recommendation for this condition. Martial's two epigrams are thus quite up to date.

Use mallows and use lettuces
That soften defecation:
For you present the facies
Of chronic constipation.
Try prunes, they're sold wrinkled and old
Brought from some foreign nation:
They'll be of use in setting loose
Thy belly's constipation.

Martial seems to have known the pathologic disturbances which result from excessive use of rich food and free indulgence in wine. Dr. Crawfurd suggests that the poet actually seems to hint in one passage that purin bodies are a cause of gout and that hepatic inadequacy is associated with the disease.

Of hares, and mullet, and sow's teat
What's the termination?
Bilious color and the feet
Racked with inflammation.

Diseases due to the disturbances of metabolism consequent on luxurious habits had multiplied greatly in Rome. What was called gout, that is, pains and aches in joints and muscles, the various forms of arthritis and the vague conditions that we now call rheumatism, had also greatly increased. Pliny, who was an older contemporary of Martial, says: "Gout used to be an extremely rare disease, not in the times of our fathers and grandfathers only, but even within my own memory." Although the gouty were usually rich and of luxurious habits, some of them, evidently, were not good pay.

Diodorus, while he sues in court,
On gouty feet can stand:
But when the lawyer's bill is brought
The gout sets fast his hand.

Evidently many counterparts of the men and manners of Martial's time could be found to-day.

WORK DURING PREGNANCY AND WEIGHT OF THE CHILD

General observation indicates that the children of working women are well developed and as strong or even stronger than the children born to women of leisure, i. e., provided the women are not too heavily taxed during the last months of pregnancy. The mothers also pass through labor as easily and safely as those who have been spared every hardship. The influence of the pregnant woman's occupation and mode of life on the intra-uterine development of the child, however, is a matter of great practical importance. Is the child of a woman who works through pregnancy actually less well equipped in the struggle for life than the child of a woman who has been able to pass through her pregnancy without hard physical work? The literature which is usually quoted seems to show the importance of rest during the last months of pregnancy. Thus Pinard gives as the average weight of the babies of women who worked up to the time of delivery, 3,010 gm. (about 6½ pounds), while the average for those born of women who had been in a maternity home for two or three months before delivery was 3,290 gm. (about 7¼ pounds), a difference of 280 gm. The statistics of Italian women given by Bordè show the same difference in favor of the resting mothers. The average of the weight of babies of Italian working women is 2,855 gm. (about 6¼ pounds), for those of women who had rested twenty-five days it is 3,248 gm. (about 7 pounds), and for those of women who had rested sixty days, it is 3,345 gm. (about 7⅜ pounds). Recently, however, Bondi[1] has disputed these conclusions and has maintained, partly on the basis of fat analyses of placentas, that the fetus develops independently and draws nutrition from the maternal body quite unaffected by the condition of the latter. He shows that corpulent women often bear small children, and vice versa. He failed in several cases to reduce the weight of the fetus by the use of the Prochownik diet. He admits, however, that disease of the mother may exercise an influence in reducing the size of the fetus.

A thesis on this subject has just appeared from the seminar of social medicine of the University of Vienna, written by Sigismund Peller[2] under the direction of L. Teleky, one of the foremost authorities on industrial hygiene. Peller contends that the authors who have discussed this subject heretofore have ignored several essential considerations. In the first place their results are not controlled; they draw conclusions from the examination of women of the working classes only without making a comparative study of women of the well-to-do, the leisure class. In the second place, they do not take into consideration the difference in development between girl babies and boy babies, and between first-born and later born. As Issmer has shown, there is a great advantage on the side of boy babies and of children of later birth, and errors inevitably arise when these differences are not considered. Peller points out the bearing this has on the assertion that illegitimate children average lower in weight at birth than do children born in wedlock. It is an undeniable fact that the proportion of first-born to later-born is very much greater among illegitimate children than is the proportion of first-born to later-born among legitimate children, for unmarried women do not tend as a usual thing to bear many children. Peller's own tables demonstrate this fact. Of the illegitimate male children 58.03 per cent. were first-born, of the legitimate only 29.83 per cent.

---

[1] Bondi: Wien. klin. Wchnschr., 1913, No. 25.

[2] Peller, Sigismund: Der Einfluss sozialen Momente auf den körperlichen Entwicklungszustand der Neugeborenen, Sonderabdruck aus dem Beiheft der Wochenschrift Das österreichische Sanitätswesen, 1913, No. 38

Peller's material was drawn from two sources, a sanatorium for women of means with 612 patients, and a large clinic for poor women with 4,875 cases.[3] He divided the poor women into two classes, those who came to the hospital just before confinement and those who were received more than a week before. In this way he could study the effect of long-continued leisure and of a more or less brief period of leisure on the weight of the new-born baby.

Leaving out of consideration the age of the mother, he finds that the first-born boy babies of well-to-do women average 120 gm. heavier at birth than those of poor women, the girl babies 92 gm. heavier. The difference is greater between children of later births. Boys of the third and fourth births in the sanatorium are 136 gm. heavier, and girls as much as 288 gm. heavier than children of the same order in the hospital. This proves the influence of social surroundings on the development of the child. Even more striking is the contrast if the Jewish sanatorium children are eliminated, for Peller found that the average weight of Jewish boy babies is 96.02 gm., and of girl babies 71.54 gm. less than that of the non-Jews, and as there were almost no Jewish babies born in the hospital, the effect was to lower the average of the sanatorium babies. Comparing the non-Jews only, the superiority of the babies of rich women over the babies of poor women who had worked up to confinement was found to be 215 gm. for boys and 150 gm. for girls.

The influence of even a short respite from hard work and probably also from anxiety and suspense is shown in the greater weight of babies born to women who came early to the hospital as compared with those of women who came just before delivery, and it must be remembered that the former were the most destitute class of all, being chiefly unmarried girls, who had no other refuge than the hospital. The difference here depends only on the care given during the last part of pregnancy, and this difference is greater than that between legitimate and illegitimate children. In a comparison of the first-born children of hospital women with those of women coming to the hospital just before confinement, the boy babies of the former are shown to average 118.11 gm. heavier and girl babies 126.42 gm. A careful tabulation of the weights of babies of hospital women shows that there is not much to be gained by keeping the mother for a long period in the hospital before confinement. What counts is the last fortnight of pregnancy. The advantage gained during these two weeks of rest from hard work is practically as great as that gained by a longer period.

The order of weight is the following: at the top the babies of the sanatorium; next the babies of hospital inmates, chiefly illegitimate; next lower, the legitimate children of women not inmates of a hospital and lowest of all, the illegitimate children of women not inmates of a hospital. So short a stay in the hospital as two weeks is sufficient to bring about the change from fourth to second place.

Several other interesting facts are brought out in this study. The most favorable age for child-bearing is apparently between 25 and 35 years, which shows that the eugenic legislation of the Spartans, which established 25 years as the age for the beginning of child-bearing, was founded on close observation. Peller's figures show that the male first-born of poor mothers between 14 and 16 years of age average only 3,124.39 gm. (about $6\frac{7}{8}$ pounds) in weight, while the same class of children of the same class of mothers between 30 and 35 years of age average 3,310.44 gm. (about $7^{3}/_{10}$ pounds).

The difference between legitimate and illegitimate children shown in Peller's tables is not so great as has been supposed. Comparing the legitimate and illegitimate of the same sex and order of birth he finds very insignificant differences, not to be compared with the difference between illegitimate children of mothers who could rest during pregnancy and those of mothers who were forced to work. The proportion of premature children is, as would be expected, highest among the unmarried mothers who worked up to the time of confinement.

The result of such a study as this should be to encourage the provision of prenatal care in hospitals and maternity homes which now too often admit the expectant mother only for actual confinement.

MEASLY MUTTON

The Bureau of Animal Industry of the United States Department of Agriculture has called attention quite recently to the extensive occurrence of sheep measles,[1] a condition hitherto commonly regarded as a sort of zoologic or pathologic curiosity. The disease is due to the encysted intermediate stage, *Cysticercus ovis*, of a species of tapeworm, *Taenia ovis,* which is harbored by the dog, precisely as man is the host of the tapeworms developed from pork and beef cysticerci. The life cycle of the latter is now well appreciated. The eggs find their way into the alimentary tract of cattle or hogs; the parasites presently reach the muscles of these animals and complete the encysted or cysticercus stage there; the "measly" meat of these mammals is then ingested by man and the development of mature egg-producing tapeworms is completed in the alimentary tract of the human host. The mutton cysticerci have hitherto been regarded by many as identical with the pork-measle parasite, which is an intermediate stage of a human tapeworm, *Taenia tenella* or *T. solium.* Ransom's investigations make it evident that these cysticerci are distinct. The *Cysticercus ovis* probably occurs wherever sheep are attended by dogs, but has not yet been found in sheep known to have originated in the eastern part of the United States. It may attain its full development in sheep in less than three months after the animals have been infected, and in the dog the tapeworm may reach egg-producing maturity in seven weeks after the ingestion of mutton containing the cysticercus.

---

[3] Craniotomies and multiple births were ruled out, and premature births were listed separately.

[1] Ransom, B. H.: Cysticercus Ovis, the Cause of Tapeworm Cysts in Mutton, Jour. Agric. Research, 1913, I, 15.

More than 17,000 of the sheep slaughtered under federal supervision during the year 1912 prior to December 1 were found to be affected with "measles," and we are assured that as the methods of meat inspection become more efficient the number of cases detected will be relatively much more numerous. The sheep cysticerci are commonly limited to the heart or diaphragm, but they not infrequently occur in other parts of the musculature. The organism is essentially a parasite of the intermuscular connective tissue and is evidently rare in other locations. Although these tapeworm cysts of the sheep are not to be regarded as transmissible to man, now that their zoologic status and life-history has been clearly made out, mutton infested with them is not a desirable article of food, and modern ideas in meat inspection require that such mutton shall either be condemned or be rendered into waste products.

Theoretically, there is no objection from the hygienic standpoint, according to government information, to passing affected mutton for food after the parasites have been removed. No great harm can be done if a few cysts of a non-transmissible parasite hidden in the musculature have escaped observation; therefore, the stringent regulations pertaining to infested beef or pork need not apply to mutton. The esthetic sense of consumers, however, as well as the current temperament in regard to such matters, tends toward the insistence on rigid enforcement of strict inspection and condemnation provisions. The logical way, therefore, to avoid the large monetary losses thereby involved will be to institute more rigid methods of prophylaxis, beginning with the dogs on the sheep-ranches.

THE OLD PRACTICE OF VENESECTION IN A NEW LIGHT

An adequate knowledge of the factors which determine the permeability of the blood-vessels remains in large part to be provided by the science of the future. It is the more to be desired because a comprehensive appreciation of the processes by which exudates and transudates are caused is likely to throw valuable side-lights on many morbid states which still defy intelligent analysis. Of late it has become more apparent that the agencies which affect the blood-vessels in the sense of altering the readiness with which the soluble contents permeate their walls may be far more diverse in character and remarkable in type than has hitherto been supposed.

It is not easy to determine experimentally in an exact and delicate way the onset of the phenomena of increased permeability which later are so conspicuous when they manifest such features as are seen when large amounts of serous fluid collect in tissue-spaces in familiar inflammatory conditions. An incipient inflammatory state of the skin with a slight attendant localized edema or urticaria may be difficult to detect, and its intensity cannot always be readily gaged. One experimental procedure has consisted in inducing a cutaneous response by the use of a local irritant like croton oil. Studies conducted in the Pharmacologic Institute of the University at Vienna[1] have indicated that the reaction thus provoked can be modified profoundly by alterations in the mode of nutrition, by intoxications or by the use of drugs. The changes in the sensitivity of the skin brought about as the result of these factors are induced only slowly, and presumably (according to Luithlen) by gradually altering the relative proportion of acids and bases in the tissue involved.

A "one-sided" dietary may effect a distinct tendency to localized cutaneous edemas, which can in turn be averted by the simple expedient of administering certain bases, such as calcium. Now it is shown, however, that more immediate responses in cutaneous susceptibility can be provoked by quite different means. By way of illustration we may cite the effects of injection, that is, parenteral introduction, of homologous or foreign serums, blood-plasma, gelatin, colloidal silicic acid, soluble starch, etc. — all substances of colloidal character which promptly decrease the sensitiveness of the skin to externally applied irritants. That this is really due to a modification in the permeability of blood-vessels is made the more probable by the fact that the same colloidal agents decrease the readiness with which injected substances find their way out of the blood-stream into the tissue fluids. When sodium iodid, or some other foreign compound, for example, is injected into the circulation it can be found sooner or later in peritoneal fluid or exudate; but if the individual has previously received a treatment with serum of various types or with some other colloidal substance, the exudative appearance of the iodid is greatly delayed.[2]

---

[1] Luithlen, F.: Veränderung der Hautreaktion bei Injektion von Serum und kolloidalen Substanzen, Wien. klin. Wchnschr., 1913, xxvi, 653.

Quite surprising is the additional fact[2] that hemorrhage, as it occurs in the old practice of blood-letting, also exercises a favorable effect in decreasing the abnormal permeability of the vessels. Accordingly, not only the injection of blood and serums, but also the repeated withdrawal of blood from the circulation may occasion a therapeutically useful response in the organism. There appears to exist in this finding an experimental basis for the old practice of blood-letting in conditions attended with the undue formation of transudates or exudates, as in pneumonia or pleurisy. The procedure, once so common and even a century ago held so generally applicable, has almost been abandoned. Like any method which rests on purely empiric basis, it has doubtless done harm incommensurably greater than the good that was expected therefrom; for so long as the underlying principle of efficiency is misunderstood or not appreciated, it is impossible to distinguish intelligently between appropriate and inappropriate applications. The good that may be accomplished happens almost as unexpectedly as the harm.

It is not unusual to find that many older therapeutic measures belonging to the days of ultra-empiricism survived because they really involved rational elements of success. Perhaps these newer studies on the effect of hemorrhage on the permeability of the blood-vessels will help to present in a better light the practice of our predecessors of a generation or two ago.

INTRAVENOUS NUTRITION

When it became obvious to physiologists that the ingested proteins are not absorbed as such or even as slightly altered digestion products and it was demonstrated that these nitrogenous foodstuffs are structurally demolished to a considerable extent before leaving the alimentary tract, various hypotheses were formulated regarding the fate of the fragments.[3] It was a prominent belief that instead of being further decomposed, the products, in passing the intestinal wall, are synthesized into protein again, with the resulting production of one or more of the proteins of the blood. As a recent writer has expressed it, this explained at one stroke both the failure to find amino-acids in the blood and the origin of its proteins. The hypothesis thus gave a serious importance to the cells forming the alimentary tube as an organ of protein synthesis.

The explanation has been shattered, however, by the subsequent finding of the amino-acids in the blood and tissues after their absorption.[3] To this may now be added a remarkable demonstration of the capacity of the animal organism to utilize its nitrogen intake when supplied completely in the form of protein digestion products introduced directly into the circulation without having traversed the digestive tube.[4] Abderhalden, in particular, has splendidly demonstrated the possibilities of maintaining animals for long periods in nitrogen equilibrium when the entire nitrogen intake was supplied in the form of amino-acids.[5] Buglia[6] showed that completely digested flesh in amounts equivalent to a day's protein requirement could be injected intravenously without injurious effect, if sufficient time were taken so that the rate of entrance of the products was similar to the rate of absorption in normal digestion. The injected products were mostly metabolized and excreted as urea. But it remained for the Danish investigators, Henriques and Andersen, to accomplish successfully the nutrition of animals solely by the route of intravenous injection of their food-supply. By attaching a cannula permanently to the jugular vein (in goats) they were able to furnish a slow stream of completely digested nutrients hour after hour to the blood-stream. The food consisted of glucose, sodium acetate and inorganic salts, together with a solution of meat completely digested with both pancreatic trypsin and the intestinal enzyme erepsin. To continue such experiments in simplified parenteral nutrition for nearly three weeks and maintain the animals in nitrogenous equilibrium or even obtain a retention of nitrogen, as the Copenhagen physiologists report, is surely a significant contribution to the study of nutrition. It confirms the newer evidence that the intestinal wall need play no rôle in protein synthesis in the organism; at any rate it scarcely seems imperative for the disintegrated protein to traverse the alimentary tube in order to become utilized in the normal manner. The apparent inactivity of the digestive appendages was shown by the minimal output of fecal matter—precisely as this occurs in starvation. The injected protein products were not rejected by the organism and eliminated through the kidneys; for day after day the urine was surprisingly like that which results when comparable foodstuffs are ingested in the usual way.

The accomplishment of the intravenous introduction of foodstuffs with evidence that they were utilized by the organism in a normal way is of more than purely theoretical interest. It brings fresh promise of potent possibilities in the way of parenteral nutrition and makes the likelihood even of successful intravenous administration of nutrients nearer realization. We have repeatedly insisted that one of the important problems for more immediate solution in dietotherapy concerns the discovery of satisfactory ways of nutrition when the oral path is excluded by considerations of disease. The perfection of rational methods of rectal alimentation and these newer indications of the tolerance of other forms of parenteral nutrition are paving the way toward such a discovery.

Current Comment

THE NEW ST. LOUIS STAR PERFORMS A SERVICE

For several years some of the Chicago newspapers carried indecent and fraudulent advertisements of local quacks. The latter part of last October the Chicago *Tribune* investigated the quack industry of the city and published the results of its investigation in a series of articles. Within a week after the appearance of the first article of this series not a single quack advertisement could be found in any Chicago newspaper. Within two months practically every advertising quack in Chicago had closed shop. Quackery cannot stand the limelight! Now comes the *New St. Louis Star,* and commencing with its issue of January 14, gives the result of its investigation into the methods of the St. Louis quacks. History is going to repeat itself, for the quacks of the Missouri metropolis are rushing to cover. Those St. Louis newspapers which heretofore sold advertising space to these swindlers have closed their pages to them, and there is every indication that St. Louis has seen the last of quackery, at least of the boldly indecent type. The *New St. Louis Star* is being supported by the better element of the city in its campaign, and a mass-meeting has been held at which the subject was discussed from all angles, both by laymen and by physicians. Particularly encouraging was the statement made at this meeting by the president of one of the large dry-goods companies of St. Louis. This gentleman, who is also president of the Civic League, discussed "The Effects of Quack Advertising on Legitimate Business." He held that legitimate advertising suffers when it appears in the same publication that carries illegitimate advertising. For this reason, he said that the St. Louis Retailers' Association, of which his firm is a member, stood ready to discontinue its advertising in certain St. Louis newspapers which carry quack advertising. This attitude on the part of reputable business men will do more to clean up and purify advertising than any other force. That the St. Louis newspapers are waking up to their responsibility in the matter is indicated by the rejection on their part, of advertisements, not only of the quacks, but also of other charlatans that have heretofore been able to purchase newspaper space. One paper is said to have accepted an advertisement of a clairvoyant a few days ago. Its owner heard of it and had the advertisement rejected even though it necessitated stopping the presses. St. Louis is to be congratulated on having a newspaper that will take up the unpleasant but necessary task of ridding the city of one of the most contemptible forms of fraud.

CHONDROITIC ACID IN DIAGNOSIS

Chondroitic acid is a complex organic acid, more properly called chondroitin-sulphuric acid, which is found in small quantities in normal urine. It has hitherto attracted little attention and there are few data indicating that it has any physiologic or pathologic importance. Pollitzer,[1] however, has published observations, which, if confirmed, will require that the clinician have a closer acquaintance with this substance. Chondroitin-sulphuric acid has been recommended as a delicate test for albumin, when added to an albumin solution acidified with acetic acid. Conversely, albumin acidified with acetic acid may be employed as a precipitant for chondroitin-sulphuric acid. Pollitzer has found that, in the presence of a serum albumin, urine containing chondroitic acid gives a precipitate on the addition of acetic acid in the cold. A large part of the precipitate which appears in the urine of patients with orthostatic albuminuria, according to Pollitzer, is due to chondroitic acid. The presence of chondroitic acid is recognized clinically by the addition of a 1 per cent. serum albumin solution acidified with acetic acid. By means of this reagent, Pollitzer was able to demonstrate the presence of chondroitic acid in young patients, even when there was no albumin in the urine. He believes that the substance is produced in the kidney by a slight degree of irritation. It is found particularly in the urine of children and young persons who are the subjects of tonsillitis or have chronically enlarged tonsils. It is not found in the urine of adults. The explanation of this fact he refers either to a modification of the action of the kidney or to the presence of some defensive factor in the throat that prevents the absorption of bacterial toxins. As stated above, chondroitin-sulphuric acid seems to be a characteristic product in orthostatic albuminuria. In this condition it may be found in the night urine which is not albuminous. If Pollitzer is right, the reaction for chondroitic acid should be included in the routine examination of the urine in children and young persons. This test may reveal a condition which needs curative treatment applied to the tonsils. Such treatment with proper hygienic measures may serve to prevent more serious disease of the kidney in later life.

REJECTIONS AND ENLISTMENTS IN THE ARMY

According to the *Army and Navy Journal,*[2] the total number of applicants for enlistment in the Army during 1913 in the Eastern, Middle, Southern and Western sections of the United States was as follows: In Chicago, 11,920, with 9,342 rejections, or 78.4 per cent. of rejections; in New York, 17,055, with 13,758 rejections, a percentage of 80.6; in Savannah, New Orleans and Little Rock, 3,855, with 3,011 rejections, a percentage of 78.1; at San Francisco, 5,504, with 4,443 rejections, a percentage of rejections of 80.7. It will be seen from these figures that the percentage of rejections was about the same in New York and San Francisco, and that the percentage for the Southern section and the

---

[1] Pollitzer, H.: Med. Klin., Dec. 21, 1913.

[2] Army and Navy Jour., Jan. 10, 1914, p. 584.

Middle West as represented by Chicago was lower than either the East or the West, with a small fraction in favor of the more northerly section. The better showing of the Middle West was rather to be expected, though the margin is quite small; but the surprising thing about all these figures is the large percentage of rejections in all sections of the country. It does not argue well for the physique and the stamina of our young men, or perhaps may be accounted for by the supposition that the best do not offer themselves for enlistment. In England, it is said, the physique of the average Tommy Atkins is deteriorating, but in a comparatively new country like the United States, the descendants of hardy pioneer stock, reared amid abundance and under favorable health and climatic conditions, should make a much better showing.

RUSSIAN ATTITUDE TOWARD JEWISH OPHTHALMOLOGISTS

Our Berlin correspondent calls attention to the agitation to prevent the success of the International Congress of Ophthalmology to be held in St. Petersburg, Russia, on account of the exclusion of some and the restrictions imposed on other Jewish members. Because of the many withdrawals from the congress, which might have been expected as the result of an appeal to the profession published by Dr. Hirschberg of Berlin, the following announcement was made early in January by Professor Bellarminoff, the head of the congress at St. Petersburg: "The minister of the interior has granted, without exception, unhindered entrance into the empire and unlimited stay to all members of the Twelfth International Congress of Ophthalmology." Apropos of this message, the editor of the *Berliner klinische Wochenschrift* says in the current issue:[1]

> It can only be a matter of keen regret that this announcement came so late, or rather was issued too late. The experience with reference to the International Medical Congress at Moscow in 1897 and the unanimous opposition which the contemplated restriction of passports met from the national committee in Germany, on the initiative of Rudolf Virchow, should have been recalled and heeded in time to spare the organization committee of the Congress of Ophthalmology this painful situation.

Medical News

CONNECTICUT

New Officers.—Hartford Medical Society: president, Dr. Everett J. McKnight; secretary, Dr. Arthur H. Griswold.

New Hospital Staff.—The following staff appointments are made by the Day Kimball Hospital, Putnam: visiting physicians, Drs. John B. Kent and Frederick A. Morrell; visiting surgeon, Dr. Seldom B. Overlock, Pomfret, assisted by Drs. Edward F. Perry, Putnam; Frank P. Todd, Danielson, and Robert C. Paine, Thompson.

Personal.—Dr. Frederick M. Wilson, Bridgeport, sailed for China, January 10.——Dr. I. Napoleon Porter, New Haven, who was operated on at the Elm City Hospital, January 3, is reported making a favorable progress toward recovery.——Dr. L. Howard Wilmot has been appointed health officer of Ansonia, succeeding Dr. Frederick C. Goldstein.

Vital Statistics for 1913.—The total deaths during the year numbered 17,726, which is 411 more than in 1912, and represents a death-rate of 15 per thousand of population, as compared with 14.9 in 1912 and 15.5 in 1911. Tuberculosis caused 1,376 deaths, 33 less than in 1912, giving a death-rate of 11.7 per 10,000 of population, as against 12.1 in 1912 and 12.7 in 1911. Pneumonia in all its forms caused 1,894 deaths, 137 more than in 1912. Deaths from typhoid numbered 129, one less than in 1912, and means a death-rate of 10.9 per 100,000 of population, which is the lowest on record for the state. Diphtheria caused 220 deaths as compared with 193 in 1912. Antitoxin was furnished free by the state. Measles and whooping-cough show a decrease, while scarlet fever showed an increase. There were 3,291 deaths of infants under 1 year of age, 139 less than in 1912. The deaths from accidents, homicides and suicides numbered 1,198.

GEORGIA

Personal.—Dr. Willard E. Quillian has been reelected president of the Atlanta Board of Health.——Dr. Allen B. Jemison has been appointed superintendent of medical inspection of the public schools of Macon and Bibb County.——Dr. Frank M. Cunningham, Macon, who has been seriously ill, is under treatment in Philadelphia.——Dr. William L. Funkhouser, Rome, has been reappointed a member of the State Board of Health in the place of Dr. Robert M. Harbin, of the same city, who declined reelection.——Dr. Ludwig Amster, Atlanta, has returned from abroad.

Memorial Hospital Established.—Drs. Hansell Crenshaw, James N. Ellis, William E. Campbell, Francis G. Jones, Crosby Swanson, G. F. Spearman, William M. Dunn, George C. Mizell, Thomas C. Hodge and Allen H. Bunce, all of Atlanta, filed a petition in the superior court, January 7, for the incorporation of an organization to maintain a hospital to be known as the Crawford W. Long Memorial Hospital, in honor of the discoverer of anesthesia. The capital stock is $4.000, with the privilege of increasing the amount to $100.000. The hospital will accommodate fifty patients, and the executive committee consists of Drs. Hansell Crenshaw, Francis P. Jones and William M. Dunn.

ILLINOIS

Sanitarium Organized.—The La Grange Sanitarium and Hospital Company has been organized and incorporated, taking over the Thornton Villa Sanatorium. The new institution will be continued under the old management, as the La Grange Sanitarium and Hospital.

Personal.—Dr. Ben B. Griffith, newly appointed head of the Springfield Department of Health, assumed the duties of his office January 7.——Dr. Howard E. Wharff, Edwardsville, fractured his right arm while cranking his automobile, January 20.——Dr. Clarence T. Roome has been appointed health commissioner of Evanston, vice Dr. S. V. Balderston, resigned.——Dr. Fred C. Dickson, Danville, has resigned from the Medical Corps, Ill. N. G.

New Officers.—Jo Daviess Medical Society at Stockton, January 15: president, Dr. Joseph C. Renwick, Warren; secretary-treasurer, Dr. Anton T. Nadig, Elizabeth.——Sangamon County Medical Society at Springfield, January 2: president, Dr. Fred S. O'Hara; secretary-treasurer, Dr. Harry C. Blankmeyer, both of Springfield.——Boone County Medical Society at Belvidere, January 15: president, Dr. Alden Alguire; secretary-treasurer, Dr. H. Eugene Delavergne, both of Belvidere.——Winnebago County Medical Society at Rockford: president, Dr. Ernest E. Ochsner; secretary-treasurer, Dr. Carl M. Ranseen, both of Rockford.

Chicago

New Officers.—Chicago Ophthalmological Society: president, Dr. Wesley H. Peck; secretary-treasurer, Dr. Paul Guilford.

Dispensary Joins Hospital.—The North Star Dispensary, which has been located near the Passavant Memorial Hospital for more than forty years, has been consolidated with the Children's Memorial Hospital.

Fight Single Isolation Hospital.—The propaganda attacking the plan for a single isolation hospital was launched January 28. The propaganda committee of the Chicago Medical Society demands four hospitals for contagious diseases, one located near the loop district, one south, one west and one northwest.

Work of Visiting Nurses.—At the twenty-fourth annual meeting of the Chicago Visiting Nurses' Association, January 22, it was reported that an average of 519 calls a day had been made by the 69 nurses on the staff. The number of patients visited was 35,523, on whom 185,757 calls were made.

Incubators for Police Stations.—The Chicago Health Department has undertaken the novel procedure of furnishing each police station in the city with electric incubators for the purpose of expediting the diagnosis of suspected cases of diphtheria. It is arranged that police officers may be handed the tubes containing the culture mediums inoculated from the throats of suspected persons as taken by the physician in charge, who will then leave them at the police station in his district where they will be immediately placed in the electric incubators. Later the cultures will be examined in the Board of Health laboratory. This plan, it is believed, will save considerable time in the diagnosis of suspected diphtheria cases.

---

[1] 1914, ii, 95.

Sanitary Trial Balance.—In the January 10 issue of the *Bulletin of the Chicago School for Sanitary Instruction*, the trial balance for 1913 was completed. During the year, a total of 45,291 deaths was reported, a daily mortality of about 97. This total includes 1,879 non-residents who died while in the city, and 915 in county and state charitable institutions just outside Chicago. The annual death-rate per 1,000, for an estimated population of 2,344,018, is 15.05; only four-tenths of 1 per cent. in excess of the average rate for the past decade. Preventable diseases claimed 15,000 victims during the years. As compared with the average rate for the past decade, this is a reduction. Deaths from tuberculosis show a reduction of 10 per cent., 3.6 per cent. in pneumonia, 36.4 per cent. in typhoid, 4.1 per cent. in diarrheal diseases of infants, 55 per cent. in influenza, and 51.7 per cent. in whooping-cough. On the other hand, scarlet-fever mortality showed an increase of 103.7 per cent., diphtheria of 33.7 per cent. and measles of 36.4 per cent.

KENTUCKY

State Health Board Election.—At the annual meeting of the State Board of Health, held in Frankfort, January 14, Dr. John G. South, Frankfort, was unanimously reelected president and Dr. Carlos A. Fish, Frankfort, was sworn in for a second term of six years.

Personal.—Dr. Thomas W. Taylor, Henderson, fractured three ribs and sustained other serious injuries in a street-car accident January 14.——Dr. Wade G. Shacklett, Pleasure Ridge Park, suffered a compound fracture of the right arm while cranking his automobile, January 14.——Dr. Augustin Diez, Lares, Porto Rico, is spending two months in study at the University of Louisville.

Staff to be Reorganized.—The trustees of the University of Louisville took steps, January 16, to begin the organization of a medical staff for the city hospital and appointed a committee to make recommendations for appointments for the hospital staff. This committee consists of Drs. Ap Morgan Vance, William A. Jenkins, H. Horace Grant, Ben. Carlos Frazier and David C. Morton.

New Officers.—Louisville Medico-Chirurgical Society, January 9: president, Dr. Henry Enos Tuley; secretary-treasurer, Dr. Frank C. Simpson.——Kentucky Midland Medical Society at Lexington, January 9: president, Dr. Walter C. Parker, Versailles; secretary-treasurer, Dr. John D. Maguire, Lexington.——Todd County Medical Society at Elkton, January 8: president, Dr. Charles M. Gower, Trenton; secretary-treasurer, Dr. Lee P. Trabue, Elkton.——Hopkinsville Academy of Medicine, organized December 23: president, Dr. James A. Southall; secretary-treasurer, Dr. Dickran H. Erkiletian.——Scott County Medical Society at Georgetown, December 23: president, Dr. Llewellyn F. Heath, Newtown; secretary-treasurer, Dr. Edward C. Barlow, Georgetown.——Jefferson County Medical Society at Louisville: president, Dr. Clarence H. Harris; secretary, Dr. Elmer L. Henderson, both of Louisville.——McCracken County Medical Society at Paducah, December 19: president, Dr. Oliver R. Kidd; secretary-treasurer, Dr. Delia Caldwell, both of Paducah.——Bourbon County Medical Society at Paris, December 18: president, Dr. William Kenny, Jr.; secretary-treasurer, Dr. Charles G. Daugherty, both of Paris.——Christian County Medical Society at Hopkinsville, December 17: president, Dr. Henry W. Watts, Pembroke; secretary, Dr. William S. Sandbach, Casky.——Fayette County Medical Society at Lexington, December 9: president, Dr. Carl L. Wheeler; secretary-treasurer, Dr. Lee C. Redmond, both of Lexington.——Bell County Medical Society at Middlesboro, December 13: president, Dr. W. L. Wilson, Pineville; secretary, Dr. O. P. Nuckols, Middlesboro.

MARYLAND

Would Do Away with Almshouses.—Dr. John S. Fulton, Baltimore, secretary of the State Board of Health, after making a special investigation of the sanitary conditions of the county almshouses throughout the state, has advised that the counties do away with almshouses and pension paupers after finding suitable homes for them.

Doctors' Orchestra Entertains Patients.—A concert was given recently at the Spring Grove State Hospital, Catonsville, by the Doctors' Orchestra, Baltimore, of which Dr. John Percy Wade is director.

Cooperative Purchasing Committee.—A cooperative purchasing committee for the five state hospitals for the insane and feeble-minded has been permanently organized with Dr. J. Percy Wade, Catonsville, as chairman. This committee does away with the employment of a purveyor; its duty will be to purchase quarterly all supplies for the institutions, and it is estimated that a saving of at least 10 per cent. on all supplies will be effected.

New Officers.—Baltimore County Medical Society, January 21: president, Dr. G. Carville McCormick, Sparrow Point; secretary, Dr. J. Carroll Monmonier, Catonsville.——Talbot County Medical Society: president, Dr. Samuel W. Trippe, Royal Oak; secretary-treasurer, Dr. Alexander McC. Stevens, Easton.——Allegany County Medical Society at Cumberland, January 14: president, Dr. James T. Johnson; secretary, Dr. Maynard J. Simmons, both of Cumberland.

Baltimore

Personal.—Dr. August F. Ries was thrown from his carriage recently, but escaped with slight injuries.——Dr. Granville Haines is said to have been adjudged insane and committed to Bay View Hospital.

New Officers.—Baltimore Society of Neurology and Psychiatry: chairman, Dr. Adolph Meyer; secretary, Dr. William Burgess Cornell.——Baltimore City Medical Society: president, Dr. Francis E. Brown; secretary, Dr. Emil Novak.

NEBRASKA

Personal.—Dr. Edward C. Lynch, Scribner, has purchased the Sacred Heart Hospital at Valentine and will take active charge of the institution.——Dr. Gilbert H. Hall, formerly of Millard, has succeeded the late Dr. Charles W. Baldwin at Elkhorn, and has been appointed district surgeon of the Union Pacific System.——Dr. James T. Kinster, Omaha, who has been seriously ill as the result of a cerebral hemorrhage, is reported to be improving.——The office of Dr. Frank Jensen, Newman Grove, was damaged by water and smoke to the extent of $500, January 10.

New Officers.—Pierce County Medical Association: president, Dr. Guy B. Desparois, Pierce.——Saunders County Medical Society at Wahoo, January 8: president, Dr. Ernest O. Weber, Wahoo; secretary, Dr. Mary A. Quincy, Ashland (reelected).——Johnson County Medical Association at Tecumseh, January 15: president Dr. Benjamin F. Gay; secretary-treasurer, Dr. Albert P. Fitzsimmons, both of Tecumseh.——Gage County Medical Society at Beatrice, January 13: president, Dr. John I. McGirr; secretary, Dr. Louis Penner, both of Beatrice.——Dodge County Medical Association at Fremont, January 8: president, Dr. Albert E. Buchanan; secretary-treasurer, Dr. Sylvester A. Preston, both of Fremont.——Burt County Medical Association at Tekamah: president, Dr. Merrit Wood, Tekamah; secretary-treasurer, Dr. Samuel A. Swenson, Oakland.——Lancaster County Medical Association at Lincoln: president, Dr. Henry J. Lenhoff; secretary-treasurer, Dr. Harry E. Flansburg.

NEW JERSEY

New Officers.—Burlington County Medical Society, eighty-fourth annual meeting at Bordentown, January 14: president, Dr. Clinton D. Mendenhall, Bordentown; secretary-treasurer, Dr. George T. Tracy, Beverly.

State Health Board Wants More Power.—The annual report of the State Board of Health especially urges that it be empowered in case of contagious diseases, should a local board of health fail to comply with the directions of the state board, to take direct control of the situation, as at present no power is invested in the state law to enforce regulations in the various sanitary districts of the state. The report also urges the continuation of the antituberculosis campaign, stating that more than 435,000 persons were interested in the "white plague" moving-picture demonstration; points out that the James cold storage act, passed in 1911, should be changed so as to require the marking of foods with the date when they are released from storage as well as the date of entrance, and also that all goods that have been in cold storage be so marked before sale.

NEW YORK

New Officers.—Newburgh Bay Medical Society, January 8: president, Dr. Henry L. Winter, Cornwall; secretary, Dr. Raymond A. Miller, Newburgh.

Tuberculosis Preventorium.—The annual meeting of the trustees of this institution was held in the New York Academy of Medicine January 20, when it was announced that $10,617 had been subscribed for the new open-air school to be established in connection with the preventorium. The capacity of the institution is now 600 children per annum, the average length of residence being three months.

New York City

New Officers.—Medical Association of the Greater City of New York, January 19: president, Thomas S. Southworth; chairman for the borough of Manhattan, Dr. Thomas Darlington; chairman for the borough of Queens, Dr. L. Howard Moss, Richmond Hill.

More Typhus.—The steamer *Kaiser Franz Joseph I* arrived from the Adriatic and Mediterranean January 18, with a case of typhus fever aboard. This is the third case of the disease discovered at the port of New York, the others coming on the *Belvidere* and the *Roma.*

Vaccination Law Upheld.—In the appeal of Hagbard Ekerold, who refused to allow his son to be vaccinated, the appellate division has ruled that parents must permit their children to be vaccinated to attend school, and that, if they refuse, they may be fined $5 for the first offense and $50 or thirty days in jail for the second offense.

Personal.—A complimentary dinner to Dr. Fanueil D. Weisse, in commemoration of his completion of 50 years as a practitioner and teacher, is to be given by his friends in the medical and dental professions at the Hotel Astor, March 28 at 7 p. m. Dr. Henry Sage Dunning, 17 East Thirty-Eighth Street, is secretary of the committee of arrangements.

New Home for Convalescents.—Vincent Astor has purchased a site for a new home for Holiday Farm at Rhinebeck-on-the-Hudson. The home is for convalescent children from the city hospitals and has been in need of larger buildings for some years. It is said that the new buildings will be ready for occupancy in the spring or early summer.

Cancer Hospital Needs Funds.—The New York Skin and Cancer Hospital in its annual report sets forth the numerous needs of that institution. It asks for contributions to be used in acquiring sufficient radium to use in the treatment of cancer and of benign growths. It is also desired to raise an endowment fund of $300,000 and a building fund of $1,000,000.

Campaign against Venereal Disease.—The city of New York has failed to make an appropriation for the work of the Division of Venereal Diseases during 1914, so the Bureau of Social Hygiene has come to the assistance of the department and has pledged sufficient money to enable the work to be carried on. Since Jan. 1, 1913, 18,750 blood specimens have been tested for syphilis and 3,526 blood specimens for gonorrhea. These were sent to the department by private physicians, clinics and hospitals, and by various social service institutions. One orphan asylum has Wassermann tests made on every child before it is admitted to the institution. A letter has been sent out to the medical profession emphasizing the fact that the Department of Health has no intention of administering treatment to persons suffering from venereal disease, and that the function of the clinics of the department are purely diagnostic and advisory.

OHIO

New Officers.—Butler County Medical Society: president, Dr. Louis H. Frechtling; secretary-treasurer, Dr. Wilmer E. Griffiths, both of Hamilton.

Personal.—Dr. F. F. Davis, East Liverpool, is ill with septicemia, due to a wound of the knee.——Dr. Howard V. Dutrow, Dayton, has been appointed district eye specialist by the State Industrial Commission.

Hospital Must Be Enlarged.—Owing to the crowded condition of the Tuberculosis Hospital at Lima, maintained by Allen, Van Wert, Auglaize, Mercer and Shelby counties, steps are being taken for its enlargement. At present thirty-eight patients are under treatment.

Ohio State University Gets Medical Department.—Reliable information states that the Ohio legislature has confirmed the action of the board of trustees of the Ohio State University in taking over the Starling-Ohio Medical College of Columbus as its medical department.

Cleveland

Reorganization of City Hospital.—Under the reorganization of the city hospital, the following staff appointments have been announced: Department of surgery, Dr. Carl A. Hamann, visiting surgeon and departmental head; Dr. Henry A. Becker, Dr. Roland E. Skeel, Dr. Oscar T. Thomas, Dr. Frederick C. Herrick, Dr. George D. Upson, Dr. Oliver A. Weber. Department of diseases of the eye, Dr. Charles C. Stuart, visiting surgeon and departmental head, assisted by Dr. William E. Shackelton. Department of diseases of nose, ear and throat, Dr. John N. Lenker, department head, assisted by Dr. Warner H. Tuckerman. Department of obstetrics, Dr. Arthur H. Bill, departmental head; Dr. John J. Thomas, assistant head; Dr. George B. Farnsworth, Dr. William T. Miller, Jr. Department of medicine, Dr. Edward P. Carter, head; Dr. Richard Dexter, assistant head; Dr. Frank J. Geib, Dr. Milton J. Lichty, Dr. Samuel J. Webster. Department of dermatology, Dr. William C. Gill, head; Dr. Harold N. Cole, assistant. Department of diseases of the nervous system, Dr. Charles W. Stone, visiting neurologist; Dr. Oliver P. Bigelow, Dr. Leonard R. Ravitz, Dr. Walter B. Laffer. Department of diseases of children, Dr. Harold O. Ruh, head; Dr. Otto L. Goehle and Dr. Frederick Beekel. Department of tuberculosis, Dr. John H. Lowman, head; Dr. Robert H. Bishop, Dr. Joseph C. Placak, Dr. Ellery P. Edwards, Dr. Cecil O. Witter. Department of pathology, Dr. William T. Howard, visiting pathologist.

PENNSYLVANIA

Sanatorium at Eaglesville.—Plans and specifications are being made for a one-story frame administration building to be erected at Eaglesville, for the Jewish Sanatorium for Consumptives.

Personal.—Dr. James S. Carpenter, Pottsville, has been reappointed district surgeon for the Pennsylvania System, for the twenty-ninth consecutive term.——Dr. Samuel P. Glover, Altoona, sailed for Europe, January 31.

Health Department Report for October.—Statistics compiled at the state department of health show that during the month of October there were 17,160 births and 8,837 deaths in the state. Penumonia caused the greatest number of deaths, 691.

Cannot Compel State Hospital to Accept Indigent Insane.—On January 19, in Quarter Sessions Court, Judge Carr filed an opinion discharging the rule, taken on the board of trustees of the State Hospital for the Insane at Norristown, to compel that institution to accept indigent insane sent there from Philadelphia.

Large State Appropriation.—Statistics compiled by the Board of Public Charities show the last legislature appropriated $16,855,391.31 for the maintenance and building for the next two years of twenty-six state institutions, seven semi-state institutions, 149 hospitals, five sanatoriums and 116 homes and asylums for the indigent and insane. In addition $2,625,000 was appropriated to the state department of health for the free treatment of tubercular patients, an appropriation of $40,000 was made for the Pennsylvania Village for Feeble-Minded Women, $250,000 for the State Industrial Home for Women and $25,000 to erect the new State Institution for Inebriates.

Philadelphia

New Officers.—Philadelphia County Medical Society, January 21: president, Dr. William Duffield Robinson; secretary, Dr. William S. Wray.——Philadelphia Neurological Society: president, Dr. Charles K. Mills; secretary, Dr. William B. Cadwalader.——Philadelphia Physicians' Motor Club, January 20: president, Dr. S. Leon Gans; secretary, Dr. Howard A. Sutton.——Philadelphia Polyclinic Ophthalmic Society: president, Dr. Wendell Reber; secretary, Dr. Walter W. Watson.

Baby Contest Closed.—The baby improvement contest, held at the Settlement House, Tenth and Bambridge Streets, under the auspices of the Child Federation, closed January 17. Final examinations of 100 babies were made and on January 21, Mayor Blankenburg awarded the three prizes of $25, $15 and $10. This contest was started eight weeks ago and all the entrants were from the Italian district. A large staff of physicians was put in charge of the work and the corps of nurses was kept busy calling at the homes of these babies. The contest not only benefited the babies, but made a marked improvement in the home sanitation.

RHODE ISLAND

Personal.—Drs. Frederick L. Blair and James Hamilton, Jr., were seriously injured in a collision between motor cars at

Providence, January 5.——Dr. Charles V. Chapin, Providence, has been elected first vice-president, and Dr. Edward C. Murphy, Providence, a director of the Rhode Island Anti-Tuberculosis Association.

Fever Outbreak Explained.—Dr. Hugh DeValin, U. S. P. H. S., who has been investigating the outbreak of typhoid fever which affected the citizens, officials and militia organizations of the state during the Perry Centennial, has reported that the epidemic was due to one of two causes, either impure water taken into the tanks of the steamer *Rochester* at various points on the trip and drawn directly from Lake Erie, or the presence on the boat of a meat cook affected with typhoid.

Organization for School Hygiene.—A movement for a state-wide organization of school superintendents and medical inspectors for the furtherance of advanced ideas on school hygiene and allied subjects, has been inaugurated in the state. A committee consisting of Drs. Gardner T: Swarts, secretary of the State Board of Health, Providence; J. Leston Nickerson, superintendent of schools of Johnston, Dr. Edgar Hamlin, Slatersville, is working on plans for the proposed organization.

TENNESSEE

New Officers.—Dickson County Medical Society at Dickson, January 6: president, Dr. William J. Sugg; secretary, Dr. William S. Scott, both of Dickson.——Nashville Academy of Medicine, January 6: president, Dr. Duncan E. Eve, Jr.; secretary, Dr. Joseph F. St. Gallagher (reelected).

Personal.—The professional friends of Dr. Richard B. Maury, Memphis, will give a dinner in honor of his eightieth birthday anniversary, February 5, at the Hotel Gayoso.——Dr. Adelbert L. Ritchey, Nashville, is reported to be critically ill at his home.——Dr. William G. Ewing, Nashville, is said to be seriously ill at his home in that city.

TEXAS

Personal.—Dr. Joseph B. McKnight, Brady, has assumed charge of the Texas State Tuberculosis Sanatorium, Carlsbad ——Dr. Walter P. McCall has been appointed local surgeon for the Houston and Texas Central Railroad at Ennis, vice Dr. John M. Hooper, resigned.——Dr. Andrew B. Parr, Gonzales, fractured his right arm while cranking his motor car recently. ——A dinner was given by medical men of Galveston to Dr Charles W. Truehart, for many years health commissioner of Galveston.

Hospital News.—The new State Hospital, Denison, has been leased to the Missouri, Kansas and Texas Railway Company. Part of the hospital is to be reserved for city patients.——Plans have been completed and approved for the new Woman's Hospital, for the Southwestern Insane Hospital, San Antonio. The building is to cost $50,000.——The Tuberculosis Clinic, Houston, was opened January 17. The clinic days are Tuesday, Thursday and Saturday.——On January 6 a free clinic was opened at St. Vincent's Sanatorium, Sherman. The institution is open each day from 1 to 3 p. m.——The new Cameron Sanatorium was formally opened January 5.

VIRGINIA

New Officers.—South Side Virginia Medical Society at Kembridge, December 9: president, Dr. Walter D. Kendig, Kembridge; secretary-treasurer, Dr. Emmet F. Reese, Courtland (reelected).

Personal.—Dr. William T. Oppenhimer, Richmond, has been appointed chief surgeon of the Chesapeake and Ohio System, succeeding Dr. Charles W. P. Brock, resigned.——Dr. George A. L. Kolmer, district inspector under the State Hookworm Commission, has resigned to enter private practice at Salem.

Society Awards Prizes.—At the meeting of the Richmond Academy of Medicine and Surgery, January 13, Dr. Charles V. Carrington, president-elect, was installed, and the following prizes were awarded for the best papers read during the year: Dr. James H. Smith, first prize, $100; Dr. Alexander G. Brown, second prize, $75; Dr. Charles M. Hazen, third prize, $25.

Hospital Loaned to City.—An ordinance was signed January 17, by the mayor of Richmond, under which the city accepts from the Medical College of Virginia the loan of the Virginia Hospital for a period of not to exceed ten years. The building is to be used as a municipal hospital until the city shall erect one of its own. A second ordinance. authorizes the expenditure of $2,600 for immediate repairs, and the building is expected to be ready to receive patients February 15.

GENERAL

Tri-State Association to Meet.—The sixteenth annual session of the Tri-State Medical Association of the Carolinas and Virgina, will be held in Wilmington, N. C., February 18 and 19.

Tri-State Society Meeting.—The fortieth semi-annual meeting of the Northern Tri-State Medical Association of Michigan, Indiana and Ohio, was held in Kalamazoo, January 13. Lima, Ohio, was selected as the next place of meeting.

Bequests and Donations.—The following bequests and donations has recently been announced:

Medford Sanitarium, Medford, L. I., N. Y., an endowment of $100,000 from an anonymous source.

Tuberculosis Preventorium for Children, Farmingdale, N. J., a contingent donation of $1,000 from Jacob Schiff.

New York Homeopathic Medical College, New York City, a donation of $25,000 for research work in cancer.

French Investigation of Postgraduate Instruction in the United States.—The minister of public instruction of France has appointed Dr. Gustav Monod, a member of the famous French Huguenot family, to report on postgraduate instruction in medicine in England and in the United States. Dr. Monod will sail for New York by the *Savoie* on February 7 and may be addressed care of the American Express Company, New York. Dr. Monod has investigated medical conditions in Paris, and while here he will probably deliver one or more addresses on this topic.

Monument to Daniel A. Carrion Proposed.—At the sixth Medical Pan-American Congress held in Lima on Nov. 11, 1913, a resolution was adopted to the effect that a monument be erected to the martyr of the medical science of Peru, Daniel A. Carrion. The cost is to be defrayed from the proceeds of subscriptions made by the American nations represented. Heads of the various delegations were charged with obtaining subscriptions in their respective countries. For the United States, subscriptions should be sent to Lieut. Col. Charles F. Mason, Medical Corps, U. S. Army, Ancon Hospital, Ancon, C. Z.

Trichinosis.—A number of cases of trichinosis have been reported from near Thomasville, N. C., with one fatality. The disease was traced to a single hog, the meat from which it is said was not thoroughly cooked before being eaten. No other instances of the disease in that section have been noted and it is thought the hog became infected from scraps of western meat fed with garbage. No cases arose among those eating the western pork because it was well cooked. Two deaths are reported from trichinosis at Stetsonville, Taylor County, Wis. Eleven persons are said to have been afflicted with the disease, due to eating raw pork.

FOREIGN

International Congress of Spanish-Speaking Physicians.—This meeting, the first of its kind, is to be held at Paris during the last half of April, 1914. Membership in the congress is open to all qualified physicians, but Spanish will be the only language used. The committee of organization is headed by Dr. A. F. Caro and includes Prof. Ramon y Cajal and Dr. A. Pulido, editor of the *Siglo Medico*, all of Madrid.

International Congress of Ophthalmology.—As already announced, the twelfth International Congress of Ophthalmology is to be held at St. Petersburg, Aug. 10 to Aug. 15, 1914. The committee for the United States includes Dr. G. E. de Schweinitz, 1705 Walnut Street, Philadelphia; Dr. E. E. Blaauw, Buffalo; Dr. A. Knapp, New York; Dr. A. Barkan, San Francisco, and Dr. W. H. Luedde, St. Louis. The subjects appointed for discussion are etiology of trachoma, and nutrition of the eye. Further particulars may be obtained from the secretary of the congress, Dr. T. Germann, Ophthalmic Hospital, Mochowaja 38, St. Petersburg, Russia, or from members of the American committee.

Other Deaths in the Profession Abroad.—Dr. A. G. del Valle, dean of the profession in Cuba, aged 99.——A. d'Antona, professor of surgery at Naples. An account of the sensational law-suit brought against him in 1904 and his acquittal was given in THE JOURNAL, March 19, 1904. He found conditions inoperable, as anticipated, in a liver affection and left two hemostatic forceps and gauze sponges in the wound, removing the forceps and some of the sponges the next day, then leaving the case, as usual, to his assistants for further care. At necropsy not long afterward a gauze tampon was found in the body and the family instituted criminal proceedings. The final trial was before the senate of the realm which resolved itself into the supreme tribunal for the purpose as Professor d'Antona was a member of the senate.

CANADA

Personal.—Dr. George R. McDonagh, Toronto, has sailed for Panama and Barbadoes.——Dr. Kennedy McIlwraith, Toronto, has gone to Naples.——Lieut.-Col. George Sterling Ryerson, M.D., Toronto, has been elected president of the Red Cross Society in Canada.——Dr. Augusta Stowe-Gullen has been reelected president of the ladies' board of the Western Hospital, Toronto.

Medical Practice Act of Saskatchewan.—An attempt has been made surreptitiously in the legislature of Saskatchewan to alter and amend the medical practice act of that province. It was all but lobbied through when it was quite accidentally discovered and then the College of Physicians and Surgeons made representations to the government to the effect that they received assurances that the bill would not be proceeded with. One of the proposed amendments was as follows: *Persons registered under the provisions of this act shall be restricted to the practice of that class or classes of practice only for which they are certified to be qualified and for which they are registered under this act.* Another proposed amendment gave the whole scheme away: All examinations of candidates for permission to practice medicine, surgery, midwifery, homeopathy, osteopathy, chiropractics, in the province of Saskatchewan shall be under the control of the University of Saskatchewan, the examiners for this purpose being appointed by the council of the university subject to the approval of the senate.

Montreal Mortality.—The total number of deaths in Montreal in 1913 numbered 11,097, or 21.7 per 1,000. The returns show an increase over 1912 of 1,412. The diseases chiefly contributing to the deaths were tuberculosis, scarlet fever, diphtheria and typhoid. Tuberculosis carried off 1,073 people, an average of 210 per 100,000, or three less per 100,000 than in 1912. The average by years for the past five years, per 100,000, was as follows: 1909, 189; 1910, 214; 1911, 194; 1912, 213; 1913, 210. From scarlet fever, 184 died as against 80 in 1912, and there was no epidemic in 1913. The records for this disease for the past five years were as follows: 1909, 27 per 100,000; 1910, 27; 1911, 16; 1912, 17; 1913, 36. Diphtheria claimed 173 people as compared with 77 in 1912. For the past five years the average for 100,000 has been in 1909, 26; 1910, 30; 1911, 29; 1912, 16; 1913, 34. Typhoid caused 106 deaths, or 21 per 100,000, or 2 per 100,000 more than in 1912. The figures for this disease for the past five years show that the quality of Montreal's drinking water has been steadily improving: In 1909, 49 per 100,000; 1910, 43; 1911, 26; 1912, 19; 1913, 21. The new medical officer of health, Dr. Boucher, is planning for a complete reorganization of the department of health, and considerable additions will be made to the staff including food and sanitary inspectors.

LONDON LETTER

(From Our Regular Correspondent)

London, Jan. 17, 1914.

A State Medical Service

In previous letters to The Journal it was shown that while the national insurance act was on the whole working smoothly and with astonishingly few complaints, considering the magnitude of the service, there were still many defects. It was also pointed out that some reformers were advocating, as a great improvement on the insurance system, a national medical service in which the physicians would be employed entirely by the state, and not only the workers would be entitled to attendance as at present, but also their dependents. This would mean that the state would provide medical attendance for the greater part of the population and convert the medical profession into a civil service. There are indications that the insurance act is only a beginning and that some such system will eventually be adopted; but the conservative character of the nation renders it probable that the change will be brought about gradually. An important pronouncement on the subject has been made by Sir John Collie, medical examiner to the London County Council and member of the Joint and Advisory Committee on Insurance (a committee consisting of physicians and laymen appointed to advise the government on questions which arise in connection with the insurance act). As he always has been a supporter of the act and a friend of the government, his views are all the more important and likely to foreshadow, to some extent at least, the official attitude. In a lecture delivered under the auspices of the Faculty of Insurance he said that after the year's experience with the act it was possible to call attention to certain revealed defects which he classified thus: defects in the act itself; defects in local administration, and defects inherent in the administration of the panel system.

The first mistake was to set up an entirely new body to administer the act. We have already too many bodies to deal with medical matters, and what is needed is coordination. The amalgamation of government medical services must come, and the Local Government Board was the proper authority to deal with this act. It would have enabled us to unite the two branches of clinical and preventive medicine. Another mistake was the creation of four commissions and the setting up of local insurance committees, "since local government is already suffering from a multiplication of bodies." In central administration the policy of the commissioners in dealing with outside bodies has too often taken the line of least resistance and yielded to demands they should have ignored. For the generous capitation sum of $1.75 for medical treatment he thought that the commissioners should have demanded a complete service. They took a disastrous step in limiting "adequate treatment" to what could be done by a physician of ordinary skill and competence. If economical and equitable arrangements had been made the physicians would have been amply paid and there would have been money to meet extra demands.

Dealing with defects in the panel system he summarized them thus: 1. *There is no selection of physicians to serve on the panel.* This is a tremendous mistake; a large number of physicians with very inferior attainments wished to put down their names, and many of them have now large numbers of insured persons on their lists.

2. There is competition between physicians for patients. This is the greatest objection to the panel system. It placed a premium on advertising, the "bedside manner," and readiness to give certificates of incapacity for work led to abuse. Much of the oversickness is due, especially among women, to genuine ill health, but there is a lot of real malingering. 3. There are too many patients on the doctor's list. No physician should be allowed to have more than a specified number of patients. "Lightning diagnosis" is a glaring defect of the panel system. 4. Owing to the absence of modern methods of scientific diagnosis, treatment is inadequate. The great bulk of the money provided under the act is going in the treatment of minor ailments; much of it is hardly more than first aid. If a person needs more than elementary treatment, it seems that he is entitled only to be informed of the fact; he must make his arrangements for treatment. In Germany full treatment is recognized as being the most economical in the long run. 5. The list of appliances is cut down to the barest possible minimum. Trusses, for example, were nearly always provided by the old friendly societies but are not included in the list.

Sir John Collie's remedy for this is a national medical service. "We must have an altogether higher conception of what is a national and adequate system. The pill and potion treatment ought to have gone forever." The new knowledge in medicine should be within the reach of every one. Hospitals, medical officers of health, consultants and others were now "practically ignored." If a really complete service were devised the objection to the act would disappear. The government should take a bold step and establish a national state medical service. Such a service should cover all the dependents of insured persons, and it should be extended to every man, woman and child of the indigent classes. It should be complete; it must provide every sort of treatment that is required. Payment should be by fixed salary; admission to the service should be by examination; administration should be both central and local. A national service would cost far less per head than the present system. Such a system should be started at once in those areas in which at present the panel physicians are overworked.

Preventive Medicine in India

The annual report of the Bombay Bacteriological Laboratory for 1912, which has just been issued, shows that during the year 700,000 doses of antiplague vaccine have been manufactured and distributed to China, Africa and Java, as well as to many places in India. Investigations into the cause, prevention and treatment of a number of diseases have also been undertaken. A large number of statistics have been collected which again emphasize the advantage of inoculation in plague. Poisons for destroying rats have been tested and experiments have been made to ascertain the most efficient means for preventing the transfer of plague infection in grain from Bombay to other ports, especially on the Persian Gulf, where plague is said to have been conveyed in steamers carrying rice from Bombay. An investigation into the prevalence of tuberculosis among cattle in Bombay is particularly noteworthy. A hundred samples of milk collected from cows in

Bombay have been examined for the presence of the tubercle bacillus, with negative results, so that it appears that tuberculosis in cattle in Bombay is extremely rare. An inquiry into the breeding places in Bombay and Karachi of stegomyia mosquitoes has been made. Both the climate and the trade of the port of Bombay are favorable for the introduction and spread of yellow fever, the Panama Canal is about to be opened for traffic, and the ports of the Far East may become infected as a result of the increased trade with the endemic home of yellow fever. It seems necessary, therefore, to take every precaution to prevent the introduction of the disease and to diminish the number of breeding places. In attempting to eradicate disease in India the great difficulties still to be overcome are the ignorance and prejudices of the people. An interesting experience at Thana is recorded in connection with guinea worm. A dilapidated well was found to be the source of the trouble. The villagers were offered the assistance of the district board to have their well put in order. They not only refused this offer but made no attempts to effect any repairs themselves. So indifferent were these people that they did not object to the village youths bathing in the well, and its contents, barely sufficient to fill a bath tub, were their only source of drinking water. A proposal has been put forward to build a new well and to protect it from contamination, but it remains to be seen if these villagers will abandon their old well and take advantage of the purer water in the new one.

PARIS LETTER

(*From Our Regular Correspondent*)

PARIS, Jan. 16, 1914.

Death of Dr. Jeanne

Dr. Jeanne, editor in chief of the *Concours médical*, has just died suddenly. Formerly a naval physician, he had devoted himself almost exclusively for some years to the defense of the interests of the medical profession. He had contributed in particular to the creation of the Mutualité médicale professionelle, and to a number of other similar societies patronized by the *Concours médical*.

Law-Suit between Dr. Doyen and an Assistant

In April, 1911, Dr. Miette entered Dr. Doyen's clinic as an assistant and consultant. December 2 Dr. Doyen dismissed him without previous notice. Dr. Miette brought suit for 500 francs ($100), representing 10 per cent. of the gross receipts of the clinic for a month, alleged to be due him, and for 4,500 francs ($900) damages for his abrupt dismissal. He was unable, however, to furnish proof of an agreement relative to a percentage, which was denied by Dr. Doyen. In the matter of damages for sudden dismissal, the court decided against Dr. Miette on the ground that there is no custom which requires a physician to give his assistant notice of dismissal, and that a physician who gives his services for certain consecutive hours of the day to a clinic near his home, and who can therefore retain his practice, cannot be placed on the same basis as an employee whom a discharge deprives of all occupation, and who is therefore entitled to notice before dismissal.

Personal

At its meeting January 13, the Académie de médecine elected M. Daniel Berthelot a member in the section of pharmacy, to take the place of M. Yvon, deceased. The new member is a son of the famous chemist, Marcellin Berthelot, and a professor at the Ecole supérieure de pharmacie de Paris.

BERLIN LETTER

(*From Our Regular Correspondent*)

BERLIN, Jan. 10, 1914.

Personal

Privat-Docent Dr. Adam has been appointed successor of the deceased Professor Kutner as director of the Kaiserin Friedrich Haus, the headquarters for medical postgraduate work.

On the occasion of the birthday of the new king of Bavaria, Professors Friedrich von Muller and von Gruber of Munich, received the title privy counselor, which carries with it the title of excellence.

Protest Against the International Congress of Ophthalmology at St. Petersburg

As the readers of THE JOURNAL must know, foreign physicians of the Jewish faith are allowed to enter Russia only by special permission of the government — a permission which is accorded only in exceptional cases, and for a short period. In order that Jewish physicians may not be excluded from international medical congresses, such an exceptional permit has generally been granted by the government for each meeting, and by this means it was possible for Jews to take part in the International Medical Congress held in Moscow about ten years ago, as well as in the International Congress of Gynecology which took place last year.

Each time earnest protests were publicly made against such an uncivilized discrimination against Jewish physicians. At the time of the International Medical Congress the protest was made by the congress itself, on the motion of Rudolf Virchow. As the same procedure is to be repeated on the occasion of the International Congress of Ophthalmology, which, according to the present plans, is to be held in St. Petersburg in August, the well known Professor Hirschberg of this city has published a statement declaring that in view of this humiliating exception he will not attend the congress, and he requests his colleagues to absent themselves as well. The president of the Belgian Ophthalmologic Society has already published a sharp protest to the same effect, and it seems as if the meeting of the congress might be endangered in this way. Such an outcome would be exceedingly regrettable for the sake of our Russian colleagues, who are entirely innocent of the inimical attitude of their government toward civilization, but it would be a generally approved reprimand to the Russian government, which probably would be made to feel that eventually it must rise to the plane of European civilization if it cares to maintain further international relations.

The excitement caused by the action of the Russian government in this matter has been considerably heightened by the recent treatment of the noted psychiatrist, Bechterew. Bechterew made a thorough and correct report regarding the recent trial for ritual murder in Kiev, which, however, was opposed to that given by the fanatical Sikorski who is probably himself suffering from a senile psychosis. The report of Bechterew was markedly unsatisfactory to the prosecution. On account of this report, Bechterew has been deprived of his office and removed from the management of the institute which was founded by him.

In view of such censorship of science and its representatives, many people have justly reached the opinion that a country which has a government of this kind at its head is not yet fit for international scientific congresses.

Industrial Insurance

As expected, the representatives of physicians and of the insurance societies reached a settlement at the meeting called by the government for December 28. That the concession was not easy for medical men was evident not only from the length of the discussions (over seven hours) but also from the fact that there were a considerable number of votes against the agreement. Many among the general mass of the profession will not be pleased with the arrangements made with the insurance societies, and very many will not be pleased with the individual provisions of the contract, but it is plain that peace with moderate concessions is always better than a war in which even the winner will suffer much loss. It must be remembered that there are a large number of physicians whose whole income is derived from insurance practice and who in the event of a conflict would need support from the Leipsic League. It must not be assumed that with the signing of the contract every occasion of disagreement is removed. Aside from the fact that a number of the provisions are not entirely clear and need an agreement from both sides as to their interpretation, there are many branch organizations on both sides that will not follow the general contract, but will make special agreements suitable to their special circumstances. Such statements have already been made by many insurance societies. One of the chief points of dispute is the position of those physicians who have made definite contracts with the insurance societies after the termination of the contracts between these societies and the insurance physicians who previously served them. These physicians are evidently able to enforce their contracts or secure some compensation. In previous conflicts the Leipsic League has undertaken to bear the cost of such a settlement. In the present case, however, it is distinctly stated in the agreement that while the Leipsic League undertakes the burden of paying the necessary compensation, the insurance societies must gradually recompense the league for half of the expense by raising their dues about 1.5 cents (5 pfennig). As this amounts to a considerable sum (it is estimated at about $250,000 (1,000,000 marks), it is evident that not all the societies are prepared to undertake such expenses which they do not believe they are bound to share.

Marriages

Jacob R. Brite, M.D., Cincinnati, Ohio, to Miss Theresa Cerwinski, both of Cincinnati, in Louisville, January 2.

Anne I. Murphy, M.D., and Mr. Arthur Belding Reed, both of Michigan City, Ind., at Oak Park, Ill., August 19.

Carl Henry Wachenfeld, M.D., to Miss Lillian Sauers, both of St. Louis, at Maplewood, Mo., January 13.

John Clarence Lindsay, M.D., Chicago, to Miss Mabel Violet Baldwin, of Bloomington, Ill., January 20.

Harold Otto von der Lieth, M.D., to Miss Eza Eugénie Saithon, both of San Francisco, January 14.

Wylie C. Johnson, M.D., Canton, N. C., to Miss Nancy Leftain of Asheville, N. C., January 1.

Thomas M. Barnett, M.D., Dothan, Ala., to Miss Agnes Bellamy of Florence, Ala., January 6.

Clarence C. Holman, M.D., to Miss Beulah Babb Crews, both of Effingham, Ill., January 17.

Joseph Bernard Winnick, M.D., to Miss Bessie Papes, both of St. Paul, Minn., November 18.

Frank Edgar Simons, M.D., to Miss Helen Sloan, both of Canajoharie, N. Y., January 13.

Timothy J. Dwyer, M.D., to Miss Flannigan, both of Omaha, Neb., January 7.

Deaths

John Spears Dorset, M.D. Long Island College Hospital, Brooklyn, 1864; a surgeon in the Confederate service and consul in London for the Confederate States during the Civil War; at one time associate editor of the *Texas Medical Journal;* died at his home in Bonham, Tex., December 7, aged 75.

Philo Milton Jewell, M.D. University of Michigan, Ann Arbor, 1873; a Fellow of the American Medical Association; formerly a member of the Iowa legislature; who was operated on last summer, died at his home in Decorah, January 8, aged 65.

James T. Graves, M D. University of Pennsylvania, Philadelphia, 1857; a member of the North Carolina state legislature in 1893, and for many years a practitioner of Wilson; died at his home near Stantonsburg, N. C., January 7, aged 78.

Elias Bruce Earhart, M.D. Cincinnati College of Medicine and Surgery, 1890; a Fellow of the American Medical Association; a member of the Board of Health of Saltsburg, Pa.; died at his home in that city, January 8, from septicemia, aged 55.

Albert A. Fitts, M.D. Howard University, Washington, D. C., 1878, of Batavia, Ill.; a Fellow of the American Medical Association; local surgeon for the Chicago and Northwestern Railway Co.; died in St. Petersburg, Fla., January 5, aged 60.

James P. Buck, M.D. Jefferson Medical College, 1879; formerly a member of the Illinois State Medical Society; a surgeon in the Servian Army during the war with Bulgaria in 1883; died at his home in Chicago, January 17, aged 57.

Joseph Longworth Anderson, M.D. College of Physicians and Surgeons, New York City, 1875; formerly of Cincinnati; who had been ill for several weeks in Johns Hopkins Hospital, Baltimore; died in that city, January 9, aged 62.

Harry P. Mera, M.D. University of Dublin, Ireland, 1858; Hahnemann Medical College, Philadelphia, 1870; for more than 30 years a practitioner of Detroit; died at the home of his son in Santa Fe, N. M., January 6, aged 78.

Staley E. Young, M.D. Baltimore Medical College, 1893; a member of the Medical Society of Virginia; surgeon for the General Chemical Company at Gossan Mines, Va.; died at that place, January 9, from meningitis, aged 51.

Rudolph Braun, M.D. College of Physicians and Surgeons, New York City, 1883; for 10 years medical inspector in the public schools of Newark, N. J.; died in his home in that city, January 9, from pneumonia, aged 62.

Erastus W. Mills, M.D. Medical College of Ohio, Cincinnati, 1859; surgeon of volunteers during the Civil War, and a pioneer practitioner of Portland, Ore.; died at his home in Hood River Valley, October 28, aged 86.

Milo E. Park, M.D. Western Reserve University, Cleveland, 1884; a member of the Medical Society of the State of Pennsylvania; county physician of Clearfield County; died at his home in Westover, January 3, aged 54.

Charles Rector Merriman, M.D. Western Reserve Medical College, Cleveland, Ohio, 1858; for many years a member of the Summit County Medical Society; died at his home in Akron, Ohio, January 9, aged 84.

George B. Campbell, M.D. St. Louis College of Physicians and Surgeons, 1892; of Port Orchard, Wash.; died suddenly while making a professional call near that place, January 5, from heart disease, aged 66.

Charles Samuel Hosmer, M.D. Rush Medical College 1893; University of Michigan, Ann Arbor, 1901; a Fellow of the American Medical Association; died at his home in Portland, Ore., December 9, aged 48.

Thomas M. Zane, M D. Missouri Medical College, St. Louis, 1877; a Fellow of the American Medical Association; of Osage City, Kan.; died in a hospital at Emporia, January 10, from nephritis, aged 61.

T. W. Fraser, M.D. Western University, London, Ont., 1886; for 20 years a resident of Mexico; died at his home on the Kingsland Road, Varina District, Va., December 31, aged 47.

John M. Dee, M.D., University of Buffalo, 1869; College of Physicians and Surgeons of Toronto, Ont., 1872; of Stamford, Ont.; died in Niagara Falls, Ont., December 2, aged 80.

Charles White, M.D. Rush Medical College, 1864; for 57 years a practitioner of Chicago; a member of the Illinois State Medical Society; died at his home, January 21, aged 82.

Charles F. Spademan, M.D. Detroit College of Medicine, 1892; a Fellow of the American Medical Association; died at his home in Detroit, January 4, from pneumonia, aged 49.

William G. Graham, M.D. New York Homeopathic Medical College, 1866; a pioneer resident of Cowley County, Kan.; died at his home in Winfield, January 2, aged 73.

Ormond Erly Hutchins, M.D. Keokuk Medical College, College of Physicians and Surgeons, 1906; died at his home in Warsaw, Ill., January 7, from pneumonia, aged 28.

Diogenes Chase, M.D. Bellevue Hospital Medical College, 1869; a veteran of the Civil War; died at his home in Morrisville, N. Y., January 7, from rheumatism, aged 70.

Duncan McAlpine, M.D. University of Toronto, Ont., 1893; L. R. C. P. Edinburgh, 1894; died at his home in Grand Haven, Mich., January 3, from pneumonia, aged 44.

John M. Fitch (license, Nebraska, 1891) for more than 25 years a practitioner of Doniphan, Neb.; died at a hospital in Grand Island, Neb., December 25, aged 77.

William Harry Harvey, M.D. Medico-Chirurgical College, Philadelphia, 1905; died at his home in Wilkinsburg, Pa., January 6, from pleuropneumonia, aged 33.

Frank S. Woolfolk, M.D. Washington University, Baltimore, 1877; a member of the Medical Society of Virginia; died at his home near Louisa, January 3.

William Odell Robinson (license, Ontario, 1869); for 45 years a practitioner of St. Jacob's, Ont.; died in his home in that village, November 1, aged 86.

John Thomas Kelley, M.D. College of Physicians and Surgeons, Boston, 1900; died at his home in Bridgewater, Mass., December 29, aged 38.

Henry Frederick Mueller, M.D. Kentucky School of Medicine, Louisville, 1889; died at his home in Sauk City, Wis., November 23, aged 53.

William T. Pulliam, M.D. Medical College of Indiana, Indianapolis, 1882; of Tuscola, Ill.; died in Tolono, Ill., November 30, aged 63.

William Roy Genung, M.D. New York University, New York City, 1852; died at his home in Fort Branch, Ind., January 4, aged 87.

Dascom A. Farrington, M.D. University of Buffalo, N. Y., 1863; died at his home in Holland, N. Y., December 30, aged 76.

Henry Flood, M.D. Bellevue Hospital Medical College, 1874; died at his home in Elmira, N. Y., about December 30, aged 62.

John J. Kirksey, M.D. Medical College of Georgia, Augusta, 1888; died at his home in Saluda, S. C., November 20, aged 59.

Samuel E. Newton (license, Utah, five years' practice, 1894); died at his home in Salt Lake City, December 29, aged 86.

D. H. Key, M.D. New Orleans School of Medicine, 1860; died at his home in Monroe, La., December 7.

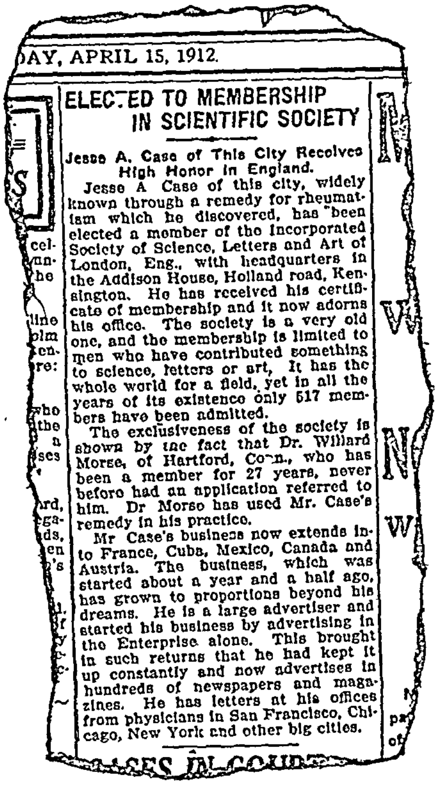
The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

CASE'S RHEUMATIC SPECIFIC

Sodium Salicylate as a Wonder Worker

"Case's Rheumatic Specific is not to be compared with any other treatment or medicine for Rheumatic diseases." So says Jesse A. Case of Brockton, Mass., "sole proprietor" of this widely heralded "specific." Mr. Case is not a physician but has after his name the letters "F. S. Sc., London." This title seems to appeal to Mr. Case for among his advertising matter is a photographic reproduction of an item appearing in a Brockton newspaper to the effect that "Jesse A. Case of This City, Receives High Honor in England." The "high honor" referred to is Mr. Case's election to "membership" in a "scientific society," namely, the "Society of Science, Letters and Arts of London." Says Mr. Case:



AY, APRIL 15, 1912.

ELECTED TO MEMBERSHIP IN SCIENTIFIC SOCIETY

Jesse A. Case of This City Receives High Honor in England.

Jesse A Case of this city, widely known through a remedy for rheumatism which he discovered, has been elected a member of the Incorporated Society of Science, Letters and Art of London, Eng., with headquarters in the Addison House, Holland road, Kensington. He has received his certificate of membership and it now adorns his office. The society is a very old one, and the membership is limited to men who have contributed something to science, letters or art, It has the whole world for a field, yet in all the years of its existence only 517 members have been admitted.

The exclusiveness of the society is shown by the fact that Dr. Willard Morse, of Hartford, Conn., who has been a member for 27 years, never before had an application referred to him. Dr Morse has used Mr. Case's remedy in his practice.

Mr Case's business now extends into France, Cuba, Mexico, Canada and Austria. The business, which was started about a year and a half ago, has grown to proportions beyond his dreams. He is a large advertiser and started his business by advertising in the Enterprise alone. This brought in such returns that he had kept it up constantly and now advertises in hundreds of newspapers and magazines. He has letters at his offices from physicians in San Francisco, Chicago, New York and other big cities.

This reproduction of a "news item" from the Brockton (Mass.) *Enterprise* is extensively distributed by Case in his advertising campaign. The "scientific society" referred to is a fake concern that sells "fellowships" at one guinea ($5.00) each to those who desire to write the letters "F.S.Sc. (Lond.)" after their names.

> "I feel proud of the fact that I have been elected a member of the Incorporated Society of Science, Letters and Art of London, England, with headquarters at Adderson House, Highland Road, Kensington. The membership is limited to those only that have contributed *something* to Science, Letters or Art."

The Journal has exposed this particular seriocomic fraud so often it hesitates to refer to it again. The "Society of Science, Letters and Arts of London" is a concern which sells "fellowships" at a guinea apiece to persons who desire to display an air of erudition by writing the magical letters "F. S. Sc. (Lond.)" after their names. As an advertising asset "fellowship" in this "society" is easily worth the five dollars it costs and, naturally, these "fellowships" are much sought by quacks and "patent medicine" venders.

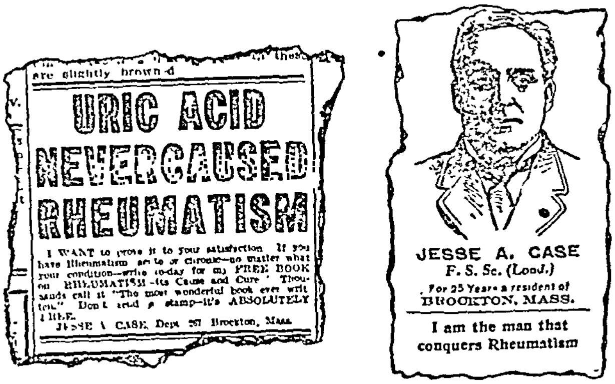
Before leaving the subject of the Society of Science, Letters and Arts, it is worth noting that Mr. Case's application for "fellowship" is alleged to have been passed on by Dr. Willard H. Morse of Hartford, Conn. Dr. Morse is a professional testimonial-giver who has furnished fake analytical reports on fraudulent consumption "cures," epilepsy "cures," blindness "cures," etc. In such a business, Dr. Morse finds the letters "F. S. Sc. (Lond.)" a useful asset, which doubtless accounts for his "fellowship" in that society.

Incidentally one of the most imposing testimonials sent out by Jesse A. Case, F. S. Sc. (Lond.), comes from Dr. Willard H. Morse, F. S. Sc. (Lond.), who testifies regarding Case's rheumatism "cure": "The Case treatment is extremely efficacious. . . . I have no hesitation in referring to this form of treatment as specific."

Jesse A. Case reaches his customers by the usual route—advertisements in the newspapers. In these advertisements he features a free book on "Rheumatism—Its Cause and Cure" and, *on these grounds*, he maintains that he does not advertise his *product*. Those who write for the book receive a sixteen-page pamphlet telling all about the "rheumatic specific." Mr. Case's claim, therefore, *that he does not advertise his preparation* is merely an example of beating the devil around a stump. He advertises his booklet and his booklet advertises his nostrum!

The direct claims made in Case's Rheumatic Specific are to the effect that it is "something different"; the inferential claim is that the stuff does not contain salicylates, for instance:

> "Case's Rheumatic Specific is guaranteed not to contain the slightest portion of any opiate of any kind or nature. No Salicylic Acid. . . ."
>
> "I also guarantee it not to contain . . . salicylic acid . . ."
>
> ". . . we have yet to learn of a single case of Rheumatism, Gout or Lumbago, where Case's Pills taken as directed did not work a cure."
>
> ". . . my treatment is not like any other."



are slightly browned

URIC ACID NEVER CAUSED RHEUMATISM

I WANT to prove it to your satisfaction. If you have Rheumatism acute or chronic—no matter what your condition—write to-day for my FREE BOOK on RHEUMATISM—Its Cause and Cure." Thousands call it "The most wonderful book ever written." Don't send a stamp—it's ABSOLUTELY FREE.

JESSE A. CASE, Dept. [illegible] Brockton, Mass.

JESSE A. CASE
F. S. Sc. (Lond.)
For 25 Years a resident of
BROCKTON, MASS.

I am the man that conquers Rheumatism

On the left: a typical advertisement of Case's Rheumatic Specific. *Because* he does not mention the name of his preparation in the advertisement but urges the reader to send for a booklet which does puff the nostrum, Case claims that he does not advertise his medicine! On the right: a reproduction of a portion of one of Case's envelopes. He misses few opportunities to feature his title "F.S.Sc. (Lond.)".

Case sells his preparation in packages of two sizes—a "ten days treatment" at one dollar and a half and a "forty days treatment" at five dollars. Those purchasing the one dollar and a half treatment receive from Mr. Case the encouraging information—after paying their money: "I do not expect that you will get any results with this small amount of medicine . . ."

Specimens of Case's rheumatic specific were obtained and the preparation was subjected to analysis. The dollar-and-a-half package comes in a small cardboard box bearing these statements:

> "Case's Rheumatic Specific."
>
> "Cures where all else fails rheumatism; muscular, sciatica, lumbago, gout, neuralgia, neuritis."
>
> "The Medicine With 10,000 Cures."

In the box are two circular pill boxes, one of them labeled, "Rheumatic and Gout Pills"; the other, "Bilious and Liver Tablets." The former are large white pills, thirty in the box; the price of these thirty pills is one dollar. The latter are yellow-coated tablets, ten in the box, price fifty cents. Our chemists examined these pills and tablets and reported as follows:

LABORATORY REPORT

"Case's Rheumatic and Gout Pills: The pills had a coating composed of calcium sulphate and sugar. After removal of the coating the pills were dark brown, somewhat soft and

of a sweet taste, resembling licorice root. The average weight of the pill, minus the coating, was 0.313 gm. (about 5 grains). The pills, freed from coating, were analyzed with the following result. Qualitatively the presence of the following was demonstrated: sodium, magnesium, calcium (small amount), potassium (small amount), salicylate, sulphate (small amount) and licorice root. The licorice root was identified by aid of the microscope. After ignition the weight of the ash was 31 per cent.—3.5 per cent. being silica and calcium sulphate, the latter probably derived from the coating.

"The pills were found to have, essentially, the following composition:

Sodium salicylate	22.4 per cent.
Magnesium Oxide	5.3 per cent.
Licorice root to make	100 per cent.

"Each pill contains about 0.06 gm. (1 grain) of sodium salicylate.

"*Case's Bilious and Liver Tablets:* These are yellow-coated tablets, the coating being composed essentially of calcium sulphate and sugar. The tablets, freed from their coating, were found to consist essentially of licorice root with aloin or some preparation of aloes, as the purgative agent. Belladonna and strychnin were not found."

From the chemist's report we learn that Case's "treatment" for rheumatism is practically the same treatment that has been used for years—the administering of salicylates. Yet in Case's booklet the inference is given that his "specific" is a herb that he discovered by chance! That pills of sodium salicylate, whether with or without licorice and magnesia, will have some effect in selected cases of rheumatism, there is no doubt. Sodium salicylate and other salicylates are given daily by physicians for certain forms of rheumatism. There is also no doubt that in exploiting his product as a "specific," in implying that it contains no salicylates and that every case of rheumatism will be cured by it, Case is perpetrating a fraud on the public. That there is money in selling pills containing sodium salicylate, licorice root and magnesia at more than three cents apiece, is doubtless true; that the public gets value received is certainly not true.

THE HORD SANITARIUM

"*Propaganda for Reform Department:*—One often hears it declared that the present time is the worst ever known for a young man to make a fortune or get a start to one.

"All a mistake, as the enclosed letter from the Hord Skinatarium will certify. At $25 this equals $2,500 for 100 cases, $25,000 for 1,000 cases, and all any young doctor needs is a little push to be as rich as J. D. in a few months. If you know of any cases send 'em in and get your $25.

"K. T. Crossen, M.D., Carbondale, Ohio."

With his letter Dr. Crossen encloses a circular letter from the Hord Sanitarium, "For Liquor and Drug Habits, A Cure Positively Guaranteed," and an unsigned check on the Farmers National Bank, Shelbyville, Indiana, for $25 payable to himself. Printed on the check in large red letters is the statement:

> "This check will be countersigned upon you bringing or sending us a patient."

The Journal has received these circular letters and unsigned checks by the hundreds from physicians who have expressed very frankly their contempt of the kind of business the Hord Sanitarium is engaged in. These correspondents seem to have overlooked the fact that The Journal has already commented editorially on this particular insult to the medical profession. For this reason we reprint the editorial note, "Ethics!" from The Journal, Sept. 27, 1913:

"We will pay you $25 for each patient that you bring or send us." Thus, to physicians, writes the Hord Sanitarium of Shelbyville, Indiana, and continues: "We have a perfect and an absolute cure for all liquor and drug addictions." Fearing doubtless that those to whom these offers are made may be disgusted with the first proposition and will realize the evident falsity of the second, the concern encloses a list of references "showing the high moral and professional standing of our sanitarium." The Hord Sanitarium emphasizes further that it does a strictly "no cure no pay" business. Suspiciously similar is the offer made by the Mizer Sanatorium of Coshocton, Ohio, Blake V. Mizer, manager. Not many months ago Mr. Mizer was running the Hord Sanitorium (the concern's own spelling), which at that time advertised "the only guaranteed cure." Now, Mr. Mizer hurls invectives at those concerns that make "unreasonable guarantees" and adds virtuously that "we resort to no such unethical and pretended guarantee in order to do business." Nevertheless, in small type in the northwest corner of his stationery, Mr. Mizer admits that his "proposition" is no cure no pay. The fees of the Mizer Sanatorium "are $125 to $250, depending on the room." The physician's rake-off is "20 per cent. of the above." "This," explains Mr. Mizer blandly, "is simply a matter between ourselves and does not concern the patient in any way." Of course not. All the patient has to do is to pay the bills. And the Mizer Sanatorium is "conducted along ethical . . . lines"—Mr. Mizer says so. The Mizer Sanatorium has odd ideas of what constitutes ethics, medical or otherwise, for not long ago it advertised, in such medical journals as would accept its "copy," that "medical ethics prevents the statement here of the whole truth about the Mizer treatment." Of course medical ethics never prevented truthful statements of any kind. A dirty business; no other words express it. When the Hord Sanitarium and the Mizer Sanatorium claim to cure all cases of drug or liquor addiction, they make claims that are false—cruelly false. When these concerns try to drum up trade by offering secret commissions to physicians they insult an honorable profession. The fact that they send out this sort of advertising matter is presumptive proof that there are some physicians who will patronize them. Such as do so are unfair to their patients and untrue to the ideals of medicine.

FOR LIQUOR AND DRUG HABITS
A CURE POSITIVELY GUARANTEED

Shelbyville, Ind.

Dec. 30th. 1913.

Dr. [redacted]

[redacted]

Dear Doctor,

The enclosed check for $25.00 will be signed and returned to you upon your bringing or sending us a patient, with the assurance that we positively guarantee a perfect and an absolute cure for each case of Liquor and Drug addiction.

Patients are not required to

Fig 2.—Part of the letter that accompanies the check for twenty-five dollars.

ANUSOL SUPPOSITORIES

To the Editor:—In the "Propaganda for Reform" department of the October 11 issue of The Journal, you published a short notice on Anusol Suppositories. We desire to correct the impression which your readers may have received, viz: that there is any actual difference between Anusol Suppositories of the present and Anusol Suppositories of the past. We wish therefore, to state that the composition of Anusol Suppositories has not been changed; the only modification that we have made is a revision of the label to the effect that the active medicinal ingredient of the preparation is a mixture of bismuth oxyiodid and bismuth resorcinsulphonate in place of bismuth iodoresorcinsulphonate. The latter was originally claimed by the manufacturers, discovered to be doubtful by an investigation in the laboratory of the American Medical Association, as well as by one on the part of a foreign chemist, and finally disproved to our satisfaction by an independent investigation on our part. We feel that the remark "What will the formula be four years hence?" will carry the impression to your readers that the composition has frequently been changed and is likely to be changed again, and it is for this reason that we request the above correction and an assurance to the contrary.

The statement in the note that "Anusol Suppositories have been proved to contain no Anusol" is also likely to create an entirely erroneous impression. We dropped the use of the word "anusol," as designating a definite chemical substance more than two years ago, and changed all our propaganda matter accordingly.

Schering & Glatz.

Correspondence

Intraspinous Injection of Salvarsanized Serum

To the Editor:—In an article on this subject (The Journal, Jan. 17, 1914, p. 183), Dr. William H. Hough, after giving the opinions of certain other workers, states that with the exception of Myerson they believe this to be the best method yet found in the treatment of paresis and tabes.

Ordinarily I should not take exception to a misquotation in a paper; but in this case, in which a new treatment is being discussed and it is very important to have the matter accurately presented, I believe that it will be of advantage to give my experience with the new form of treatment.

Contrary to Dr. Hough's statement, I believe salvarsanized serum to be the best form of treatment for paresis and tabes which we have yet devised. The results quoted in my report in the *Boston Medical and Surgical Journal*, Sept. 18, 1913, and my statement at that time, indicate this so plainly that I am surprised at the position assigned to me by Dr. Hough. At a discussion in the Boston medical library a short time ago, however, I did state that we were not going to *cure* paresis, in my judgment, by this new treatment. I believe that we can influence its course but cannot cure it. I stated at that time my reasons for this belief, as follows:

First, none of my patients showed any very marked clinical improvement which was permanent and could not be credited to a remission of paresis.

Secondly, this treatment, so far as it applies to paresis, is based on a fallacy; this fallacy is that the nervous system, especially the brain, is not accessible to medicaments introduced into the blood-stream. The effects of opium, strychnin, chloral, bromid and a dozen other drugs, as well as the fact that the brain is readily supplied with blood-vessels which permeate to its deepest parts, absolutely disprove this. When a substance does not affect the nerve-cells, it is because its chemical and biologic properties make a union between them impossible, not because of any remoteness of the nervous system in relation to the blood-stream. Furthermore, it is assumed that a substance introduced into the spinal canal penetrates the nervous system better than does a substance introduced into the blood-stream. The fact that the normal flow of the spinal fluid is *away from* the nervous system contradicts this.

For local diseases, intradural injection is of paramount importance. For example, cerebrospinal syphilis, meningitis and tabes, in which the initial meningitis is of moment, offer a good field; but in paresis, the damage reaches deep into the nervous substance, and the blood-stream has better access to this than the cerebrospinal fluid.

In conclusion, let me state again that I believe this treatment is a good one in nervous syphilis and ought to be used even in paresis, or at least tried out. My results, however, which I shall publish in detail later, as well as theoretical considerations, make it seem unlikely to me that a permanent cure or arrest of paresis is possible with this treatment.

A. Myerson, M.D., Taunton, Mass.

Report on Subscription Funds

To the Editor:—I beg to make two financial reports through The Journal to the donors as follows:

THE LISTER MEMORIAL FUNDS

A. For the Lister ward in Glasgow		$ 28.50
Of this there were forwarded to Mr. Ernest Maynard in Glasgow, Jan. 13, 1913	$ 25.00	
and to Mr. John S. Samuel, Hon. Treas., in Glasgow on May 3, 1913	3.50	
		$ 28.50
B. Undesignated subscriptions	$433.50	
Interest over and above expenses	1.70	
		$435.20
This was forwarded to Mr. Samuel May 3, 1913:		
C. For Tablet in Westminster Abbey	$ 5.00	
D. Undesignated subscriptions	433.50	
Interest over and above expenses	1.70	
		$440.20
This was forwarded to Sir W. Watson Cheyne, London, May 2, 1913:		
E. For the International Memorial Fund in London from the American Gynecological Society per Dr. J. Wesley Bovée, Treasurer, Washington, and forwarded to Sir W. Watson Cheyne, Jan. 16, 1914		$100.00
F. Undesignated contributions	$142.50	
Of this $127.50 were from members of the American Dermatological Society per Dr. Oliver S. Ormsby of Chicago..		
Interest over and above expenses	.92	
		$143.42

The undesignated funds, $143.42, were sent one-half to Mr. Samuel in Glasgow and the other half to Sir W. Watson Cheyne, Bart., in London, on Jan. 16, 1914.

The sum total, therefore, forwarded through me has been:

For the Lister ward in Glasgow	$ 28.50
Undesignated funds to Glasgow	435.20
For the tablet in Westminster Abbey	5.00
Undesignated funds to London	435.20
For the International Memorial Fund in London	100.00
Undesignated Funds, half to Glasgow and half to London	143.42
	$1,147.32

I should mention the very active interest in obtaining subscriptions shown by several friends, but especially by Dr. A. Vander Veer of Albany, N. Y., and Dr. Thomas W. Huntington of San Francisco. The zeal of Dr. Huntington seemed inexhaustible.

Besides the funds which I have been privileged to forward there have been forwarded:

From the College of Physicians of Philadelphia	$ 206.00
Through Dr. Lewis S. Pilcher from members of the American Surgical Association, including $500 subscribed by the Association from its own treasury	1,317.97
Amounts reported above	1,147.32
Total	$2,671.29

Not a few Fellows of the American Surgical Association and of the College of Physicians of Philadelphia sent contributions to me before the matter was taken up by these societies as such, and many others, members of other societies, have done the same, so that various national organizations, even unnamed ones, are really represented. There may have been also personal gifts made directly to London and Glasgow.

THE CANTEEN FUND

This money was contributed to print, obtain signatures to, and circulate a petition to Congress to pass the bill (H. R. 30) and thus to reestablish the so-called "canteen" in the United States Army.

My letter was dated Oct. 18, 1911, and I asked for $2 contributions. I stated that if any small balance finally remained I would give it to the general endowment fund of the Library of the College of Physicians of Philadelphia.

Amounts contributed in sums of $1 and $2................	$283.79
Expenses for printing, postage, express, etc...............	227.91
Balance on hand	$ 55.88

For this amount I have handed a check to Dr. George Fales Baker, treasurer pro tem. of the College of Physicians, on Jan. 17, 1914. W. W. Keen, M.D., Philadelphia.

Queries and Minor Notes

Anonymous Communications and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

COLORED PROTECTIVE EYE-GLASSES

To the Editor:—What should be the color of glasses to protect the eyes against reflected sunlight, as from snow and water; also against wind?

What should be the shape of the lenses when refraction is normal?

I have been requested to advise patients in this regard. There appears to be some difference of opinion as to the color, blue, green, "smoked" and amber being recommended. Recently I read an article recommending a combination of green and yellow. E. T. H.

Answer.—These questions require different answers, as on the particular form of irritation to which the eyes are exposed depends the color of the glass which will afford the greatest degree of protection.

From our knowledge of the effect of rays of light of different wave-lengths, it has been possible to study this problem scientifically. We know that the rays of shortest wave-length are at the violet and ultraviolet end of the spectrum. These actinic rays, as they are commonly called, on account of their action on some of the silver salts, are also known as the chemical rays; they are made use of in photography. The rays of longest wave-length are the red and infrared rays, situated at the opposite end of the spectrum. These are known as the heat rays.

Persons exposed to strong sunlight, to the glare of water or the reflection from snow or from chalk-cliffs, suffer from the action of the actinic rays. The glass which possesses the greatest power to shut out these rays, and at the same time permits of the greatest amount of illumination, has been found to be a shade of amber. This may readily be demonstrated by looking at the spectrum through an amber-colored glass.

In a series of experiments made a number of years ago, Dr. Fieuzal demonstrated quite conclusively that a certain tint of amber, containing more of the green than the amber commonly used (which is more yellowish), had the greatest effect in excluding the maximum amount of actinic rays while excluding the minimum amount of illumination. The Fieuzal glass therefore gives one almost normal perception minus the irritating constituent of the light, and with the least change in the natural colors of visible objects.

In ametropic conditions, the proper correction can be ground on lenses thus tinted, and worn constantly if desired. The most suitable form of lens for this purpose is the large oval shape, ground on toric or meniscus lenses; they should be worn as close to the eyes as possible, to shut out any rays that might enter the eye around the edges of the lens. For persons in somewhat unusual situations, such as persons on an ocean trip, chauffeurs, locomotive engineers, aeronauts, etc., when temporary protection from sun and wind is desired, a most excellent device is the so-called "auto-glass" *made in* an amber tint. The lenses, joined over the nose by a hinge, are so large that they touch the cheek below and forehead above; they have the toric curve, and fit snugly to the face on every side. In this way they protect the eyes perfectly from both wind and glare, but their large size makes them too ungainly for ordinary street wear.

Certain occupations necessitate constant exposure of the eyes to intense heat as well as to strong light; glass-blowers and those employed about blast-furnaces suffer from this form of irritation. Under such conditions the eyes should be protected as much as possible by glasses which most effectively shut out the heat rays, at the same time affording sufficient illumination. This result is best obtained by a shade of blue. A much greater amount of illumination is excluded by blue than by amber, and hence it is unwise to attempt to protect the eyes by blue glasses while reading either by sunlight or artificial light, as the illumination is so much reduced that the effort to see clearly would cause added strain to the eyes. Amber glass furnishes the needed protection without very much diminishing the illumination.

It can be stated as a safe rule that smoked glasses should be worn only when prescribed by an oculist.

In certain inflammatory conditions in which it is unnecessary or even undesirable to bandage the eyes, smoked glasses are sometimes used; but this class of cases forms a group by itself and should not properly enter the present consideration.

THE PHYSICIAN AND THE MANUFACTURING PHARMACIST

To the Editor:—1. Is it ethical for a practitioner of medicine to own stock in a corporation which manufactures pharmaceuticals?

2. Is it right for a physician who owns such stock to prescribe the preparations manufactured by the corporation?

3. Is it right for a physician to hold a financial interest in or to participate actively in the business management of such a corporation, even if he prescribes the firm's products only when honestly indicated and because he believes in them, and because he has nothing but the patient's welfare at heart?

B. C. A., M.D., New York.

Answer.—1. Can a practicing physician, a human being, avoid being biased—just a little—in his judgment of the pharmaceutical products of a manufacturing corporation in which he holds stock? Unless he keeps his connection with the company secret from his patients and his fellow practitioners, would he not constantly be on the defensive? Do not answers to these questions show such a position to be far from ideal?

2. It is "unethical to prescribe or dispense secret medicines or other secret remedial agents, or manufacture or promote their use in any way" (Section 6, Article 1, Chapter 2, Principles of Medical Ethics). If the products are not secret, prove by questions suggested in Answer 1 before prescribing them.

3. That little word "if" is important. Again the question: Can the ordinary human being avoid being biased under the circumstances?

JACKSON'S MEMBRANE—EFFECT OF REMOVING THE TONSILS

To the Editor:—1. What is Jackson's veil?

2. The statement has been made that the complete removal of the tonsil in a small child is apt to result in asexualization of the patient. The operator making it had partially removed them in a specific case and when subsequent hypertrophy of the remaining portions began to cause considerable inconvenience, the statement was made as a reason for the incomplete removal at the first consultation. Is there any authority for the statement being true in any degree? X. Y. Z.

Answer.—1. Jackson's veil, or membrane, is a delicate membrane extending from the parietal peritoneum of the right flank across the front of the ascending colon to the inner side and continuous above with the transverse mesocolon.

2. Some authors have asserted that the tonsils have an internal secretion, but this assertion is not sufficiently recognized to secure the tonsils a place in the usual lists of ductless glands. Chassaignac is credited with believing that the hypertrophy of these organs tends to hinder the development of the genital organs, thus forming an indication for their removal. There is no reliable evidence that the removal of the tonsils has any deleterious effect on the general condition, but there is abundant proof that the results are in many cases decidedly beneficial.

LESSENED ALKALINITY AND NERVOUS BREAK-DOWNS

To the Editor:—Could a lessening of the alkalinity of the blood be the cause of periodic nervous breakdowns? H. M. M.

Answer.—Not enough is known with reference to the reaction of the blood in various diseases to make it possible to say what the effect of a lessening of the alkalinity would be. To assign it as the cause of a nervous breakdown would be a plausible but very hypothetic and uncertain explanation. It would be an evading of the real question, for the lessening of alkalinity and the nervous affection are each probably the result of some underlying cause.

DISSEMINATION OF MEASLES

To the Editor:—What is the present understanding in regard to the dissemination of measles?

H. H. Ainsworth, M.D., Cody, Wyo.

Answer.—Measles is communicated mainly by contagion. Fomites play a very small part in transmission. The disease is communicable during the prodromal fever and the period of eruption. Some believe that contagion may also be found in the discharge of the nose and ears. Patients with measles should be isolated until the eruption has disappeared.

Medical Economics

THIS DEPARTMENT EMBODIES THE SUBJECTS OF POST-GRADUATE WORK, CONTRACT PRACTICE, LEGISLATION, MEDICAL DEFENSE, AND OTHER MEDICOLEGAL AND ECONOMIC QUESTIONS OF INTEREST TO PHYSICIANS

INDUSTRIAL STRUGGLES OF PHYSICIANS ABROAD

The dispute in Germany between the insurance societies and the medical profession, which threatened to come to a crisis with the first of January, apparently has been averted, for the time being, through the mediation of the universities, which have endeavored to bring the disputing parties together.

The German secretary of state for home affairs, with the Prussian ministers of trade, agriculture and the interior, the three ministers in whose hands the enforcement of the law is placed, received a delegation from the German universities representing the medical faculties. These representatives presented the claims of the medical profession and urged that they be given careful consideration by the government, and that every effort be made to prevent the newly enacted insurance law from being rendered incapable of enforcement, to the injury of large numbers of insured laborers. The result of the conference was that the secretary of state for home affairs agreed to make an effort to bring about a settlement which would be satisfactory to both sides of the controversy, while the representatives from the universities agreed to use their influence with the medical profession to secure the acceptance of reasonable conditions. The terms which were finally agreed on provided for a district committee for each insurance area, consisting of equal representation of the medical profession and the insurance societies, with a chairman for each committee who shall be neutral and probably appointed by the government. These district committees will be empowered to formulate contracts for medical services which must comply with certain definite conditions, to make a list of physicians who are willing to serve in the districts as insurance society doctors, and to act as a committee of arbitration in the settlement of disputes. The agreement provides that the rate of remuneration shall not, under any circumstances, be less than 25 marks—$6.25—per year per person, and that the district committee can increase but cannot reduce this compensation below this minimum. Insured persons are to have the privilege of choosing any physician from the list prepared by the committee. All existing contracts are to be confirmed, but agreements made by the societies with physicians for the purpose of compelling the medical profession to accept the terms offered by the societies are to be canceled and the physicians interested are to be compensated for such termination of contract, the funds for the annulment of such contracts to be equally subscribed by the insurance societies and the physicians' organizations.

As the points under dispute were the representation of physicians on the local committees, the amount of fees and the status of those physicians who were being used by insurance societies to force the acceptance of their terms, the agreement can be regarded as a satisfactory victory for the German medical profession. The conditions under which the existing contracts of the so called "strike breaking doctors" are canceled is worth noting. The medical profession and the insurance societies, the two bodies most interested, united in furnishing the necessary funds for buying up and canceling these contracts.

The agreement provides that new contracts are to be signed by individual physicians and not by medical organizations. They are to cover a period of ten years. When the terms were submitted to the medical societies they were at first somewhat criticized, but the fact that they provided for arbitration of disputes and for the cancellation of contracts of those physicians who had not conformed to the agreement adopted by the bulk of the profession finally led to their acceptance. According to the Berlin newspapers, the entire conflict has been a benefit to the profession, in that it has brought them together and strengthened their organization in a way that nothing in previous years has done. This is particularly true of the larger cities, where the medical organizations have heretofore been weak.

In Great Britain the discussion over the operation of the insurance act continues. A recent article in the London *Times* under the title "The Revolt of the Junior Medical Officer" discusses the prospects of the young physicians under present conditions, laying special emphasis on the growing demand for increased compensation for junior medical assistants in hospitals and sanitaria and in private practice. Commenting on this article, the *British Medical Journal* says editorially that while the compensation for assistants has undoubtedly advanced, it has been advancing for many years, and this advance is not due to the insurance act. This is also true of the demand for increased compensation among ship surgeons. The *Journal* denies that the insurance act will produce any embarrassment of riches among physicians in cities and in industrial centers. It admits that certain physicians in certain industrial districts have benefited by the practice of the act. "It is true," says the writer, "that for a certain class of men from whom under previous conditions they (practicing physicians) received little or nothing the doctors are now receiving remuneration, but this must be discounted by the lowering of the rates in other grades of insured persons, such as highly skilled artisans, clerks, shop assistants and others." The truth seems to be that while physicians are not paid as much for the same services as they formerly charged, or claimed to charge, yet they are being paid for a larger percentage of their work than formerly and are relieved of some of the uncertainty and expense of collecting bad debts, etc.

At a recent meeting of the National Medical Guild of England, the question of trade unionism in the medical profession being under discussion, the president of the guild stated that the organization was registered under the "Trades Union Act" and called attention to the need of cohesion in the medical profession to meet the present economic situation. One speaker in favor of medical trade unionism declared that under existing conditions such a union was practically a necessity, that the whole question of state insurance would be opened up for general discussion, and that the medical profession must be better prepared to defend its interests than it was in the recent struggle. Many of the insurance societies considered the present morbidity rate abnormal and felt that physicians were being paid too much for their services. As a result, they will unquestionably make an effort to reduce the rate of compensation to physicians at the first opportunity. In order to protect the rights and interests of physicians it would be absolutely necessary to have an ample supply of funds which could be secured only by the organization of a medical union. The speaker argued that the British Medical Association should become a trade union on one side of its work and a scientific body on the other, if this were possible from a legal point of view. Representatives in Parliament, as well as an organization that would be capable of prompt action were also necessary. Politicians, insurance societies and the general public were supporting a proposition for a state medical service which would be most injurious to the profession and which would be effectively opposed only by a properly organized and united profession. Another speaker deplored the apathy of physicians and the difficulty of arousing them to activity in their own interests. Further discussion was in favor of and led to the adoption of resolutions pledging the support of the organizations to a trade union in the medical profession which would have the machinery and the means for defending the interests of physicians.

In Belgium the semicentennial of the Belgium Medical Association finds 75 per cent. of the profession in the country enrolled as members. According to the *Gazette médicale belge*, only the lack of local associations to which they can belong keeps many others from joining. In German Bohemia the profession is exceptionally well organized and united. In each week's issue of the *Prager medizinische Wochenschrift* appear directions to members regarding places to be avoided in selecting locations.

Conference on Premedical Education, and Installation of Dean Holmes at Cincinnati

A special celebration was held in Cincinnati, Friday, January 16, on the occasion of the installation of Dr. Christian R. Holmes as dean of the Ohio-Miami Medical College, the medical department of the University of Cincinnati. Dr. William H. Welch of Johns Hopkins was the principal speaker and about forty representatives from various medical and liberal arts colleges were present. At the close of the ceremonies a portrait of the late Dr. Frederick Forchheimer, one of the founders of the medical college, was presented by Dr. Robert Stewart and was accepted by President Dabney on behalf of the university. The painting was the gift of Mr. and Mrs. William Mosler and was executed by the artist Henry Mosler, brother of the donor.

The installation of Dr. Holmes as dean of the university's medical department marks another epoch in the development of that school. Dr. Holmes has been the guiding spirit in the planning and erection of the new Cincinnati City Hospital, which is probably the most remarkable institution of its kind in the country. Meanwhile it is important to note that the medical department of the University of Cincinnati is to have entire control of the teaching facilities furnished by this hospital.

Saturday morning the guests were taken in automobiles on a tour of inspection, visiting first a portion of the medical school and then the various buildings of the new city hospital. At a special luncheon held in the university buildings Saturday noon a special conference on premedical education was held. Dr. William H. Welch was the first speaker, and referred to the problems confronting medical education, particularly of the need generally of a closer cooperation between medical schools and hospitals. Following the talk by Dr. Welch, Dr. N. P. Colwell, Secretary of the Council on Medical Education, presented the main problems in the administration of preliminary requirements. The statement was made that the greatest need was a routine by which the preliminary credentials of the medical student would be carefully verified, beginning with the work taken in the high school, and that these preliminary requirements should be so administered as not to hinder but rather aid in the development of the secondary schools.

Papers were then read by Henry B. Ward of the University of Illinois, on the teaching of zoology; by Michael F. Guyer of the University of Wisconsin, on the teaching of biology; by Lauder William Jones of the University of Cincinnati, on the teaching of chemistry; by President Brown Ayres of the University of Tennessee, on the teaching of physics, and by Vice-President Edgar E. Brandon of Miami University, on the teaching of modern languages. Following the conference some resolutions were adopted looking toward greater uniformity in the teaching of these premedical subjects and toward future conferences should they become necessary.

Saturday evening a special banquet was held at the Sinton Hotel, which was attended by about three hundred citizens of Cincinnati. At this banquet Dr. C. A. L. Reed acted as toastmaster, and the speakers of the evening were Dr. Holmes, Mayor Spiegel of Cincinnati; Dr. Welch; Dr. John A. Witherspoon, President of the American Medical Association; Dr Arthur Dean Bevan, chairman of the Council on Medical Education, and Mr. James Albert Green, a prominent citizen of Cincinnati. Dr. Robert S. Brookings of St. Louis, whose name appeared on the program, could not be present, but telegraphed an address of several hundred words, which was read.

Book Notices

INDIGESTION, CONSTIPATION AND LIVER DISORDER. By G. Sherman Bigg, Fellow of the Royal College of Surgeons, Edinburgh, [illegible] Native Followers' Hospital and Women's [illegible] ndia. Cloth. Price, $1.50. Pp. 163. New [illegible] 1913.

The subject of this book would form an excellent topic for an up-to-date work, for there is no field in which the expansion of medicine along the lines of modern research has been more marked. Certainly there is no subject of greater practical importance, for on the efficiency of the digestive apparatus depends the health of the individual. And yet, to the consideration of this topic the author brings the conceptions and therapeutics of the last century. There is scarcely a hint of modern diagnostic measures except that the Roentgen ray is occasionally mentioned. After the crudest explanation of the digestive process, the author enters on his task of prescribing. He slights dietetics and seldom inquires as to the underlying condition from which the symptoms result. As an example of the clearness of the advice given, we quote: "The question whether to begin treatment with an acid or an alkali is a matter for discrimination and can only be decided by a consideration of the existing symptoms, but in all cases of doubt it is wise to begin with an alkali as more likely to produce a satisfactory result." No hint is given as to what symptoms will indicate either acid or alkali, nor to what pathologic conditions the symptoms point. It is not suggested that the condition of the stomach could be determined by examining the stomach contents. "As regards dieting in indigestion," we are told, "the food which agrees best is the most suitable nourishment. . . ." Thus we are rid of all dietetic difficulties.

The following is the teaching regarding acidity:

"Acidity of indigestion results from fermentation of food and the subsequent formation of deleterious acids." The author seems unaware of the infrequency with which fermentation takes place in the stomach. To show that he is aware of the existence of hyperchlorhydria he adds, "It may arise, also, from excessive secretion of the natural acid of the gastric juice." A very injudicious feature of the therapeutics taught in this work is the frequency with which opium is resorted to for the relief of pain and distress in the digestive tract—a teaching that is to be emphatically condemned. The danger of producing a habit seems to be entirely disregarded.

Another interesting feature is the rather complete list of the proprietary specialties of a prominent English pharmaceutical house and a similar one of a noted American manufacturer. We do not mean that these are separate from the rest of the book; they are scattered throughout the work, appearing on nearly every page. The well-advertised Antikamnia, Antiphlogistine, Lactopeptin, Chionia, etc., are not neglected. The book is a genuine storehouse of nostrums, especially of the antidyspeptic variety. The author evidently was so fascinated with the claims of nostrum promoters that he could not keep them out of his prescriptions. The book illustrates the disgraceful fact that British medical men are to a large extent under the domination of proprietary interests. What is more discouraging, there seems to be no voice in the medical press raised against this abominable evil.

Malaria: Etiology, Pathology, Diagnosis, Prophylaxis and Treatment. By Graham E. Henson, M.D. With an Introduction by Charles C. Bass, M.D., Professor of Experimental Medicine, *Medical Department Tulane University. Cloth. Price, $2.50.* Pp. 190, with 27 illustrations. St. Louis: C. V. Mosby Company, 1913.

The importance of malaria as an endemic and yet preventable disease renders *a treatise on this subject of especial* interest at the present time. The measures necessary to combat this disease are similar to those which have been so successful in the extermination of yellow fever. On a small scale they have been successfully employed in Panama and in various localities in this country and India. The widespread character of the disease, however, has created a certain indifference to it, which has prevented the attempt at a thorough eradication. The work of Dr. Henson is well calculated to supply the knowledge necessary for a thorough campaign against the disease. Beginning with a study of malarial parasites, he describes the various forms and development of the organism, both in the blood and in the mosquito. The various malaria-bearing mosquitoes are also thoroughly described. The author then passes to the subject of the disease itself, which he discusses in considerable detail. It is singular, however, that we cannot find that he has mentioned blackwater fever, which is usually regarded as a symptom or a complication of malaria. With this exception, the discussion of the disease appears to be sufficiently detailed. A long chapter is devoted to the matter of diagnosis, both microscopic and clinical. The matter of prophylaxis is well treated, both from a public health and from an individual point of view. The subject of treatment amounts mainly to the methods of administering quinin. Other methods, such as, methylene blue, treatment with Roentgen rays, etc., are given very brief consideration. The book is well illustrated, and will undoubtedly prove useful to a large class of readers.

A Reference Handbook of the Medical Sciences Embracing the Entire Range of Scientific and Practical Medicine and Allied Science. By Various Writers. Edited by Thomas Lathrop Stedman, A. M., M.D. Third Edition. Volume Two. Cloth. Price, $64 per set of 8 volumes. Pp. 882, with 365 illustrations. New York: William Wood & Co., 1913.

This volume covers a number of important subjects, which are given a treatment adequate to their importance in a form equivalent to separate treatises. Thus the subject "blood" with several subtitles occupies nearly ninety large pages, while the brain is discussed in more than 160 pages. The article on blood is extensive and describes in detail the methods of clinical examination. Thus the various steps in taking blood for clinical examination are illustrated by various figures showing the exact position of the hands of the examiner and the nature of all the manipulations. Under the examination of blood-stains the precipitin method is fully described, and the complement-fixation method is noticed but not recommended on account of its complexity and uncertainty. The histology and pathologic anatomy of the blood-vessels occupies twenty pages closely packed with detailed information. An article on cardiography includes the subject of the electrocardiograph, which is explained. Other minor subjects maintain a similar degree of excellence. This volume contains a large number of interesting contributions to medical biography, including a number of names of men and women who have made striking contributions to medical progress. A number of these are American, particularly Beaumont, Elizabeth and Emily Blackwell, Brainard and Buck. In every article are evidences that the information has been brought thoroughly up to date and is encyclopedic in character. The numerous and excellent illustrations add materially to the value of the book.

Dysenteries: Their Differentiation and Treatment. By Leonard Rogers, M.D., F.R.C.P., B.S., Physician to the Isolation Ward (Cholera and Dysentery), Medical College Hospital, Calcutta. Cloth. Price, $3.75. Pp. 336, with illustrations. New York: Oxford University Press, 1913.

It is an interesting fact that even within the last two decades there was no place for a book with this title, as up to that time there was no general agreement as to the existence of more than one form of dysentery. The author, who has taken a considerable part in the differentiation of the various forms of dysentery, treats the history of this development and shows that before the separate action of amebas and bacilli was recognized there was a division which, to a certain extent, corresponded to the present etiologic classification; that is, dysenteries were classified as simple dysenteries and those complicated with hepatic abscess. The latter class consisted almost invariably of forms of amebic dysentery. It is interesting to note the practical priority of American research in the differentiation of these two forms. Aside from the main forms of amebic and bacillary dysentery, the author recognizes the *Balantidium coli* and the *Bilharzia haematobia* as capable of producing dysenteric symptoms. The pathogenic action of the *Trichomonas intestinalis* and of the intestinal worms is not settled. In connection with the subject of dysentery the diarrheas of unknown origin, known as hill diarrhea and diarrhea alba or sprue, are briefly discussed. The author naturally places marked emphasis on the treatment of amebic dysentery by salts of emetin, and suggests the possible value of this remedy for balantidium and bilharzia. *The work is well illustrated, chiefly by pictures of pathologic* specimens, several of which are presented as colored plates.

Disease and Its Causes. By W. T. Councilman, A.M., M.D., LL.D., Professor of Pathology, Harvard University. Cloth. Price, 50 cents. Pp. 254, with 22 illustrations. New York: Henry Holt & Co., 1913.

In this volume Councilman has given a general view of diseases *for non-medical readers, considering it as the mani*festation of life in an organism not in harmony with its environment. The conception of disease as a manifestation of life necessitates a review of the properties and the characteristics of living matter. A large part of the book is devoted to describing the causes of the infectious diseases and the changes which the tissues undergo as a result of infection. A good historical review of the gradual discovery of the relation of micro-organisms to disease is given. The real inheritance of disease is denied, although the frequent transmission of infection along with the germ-cells is emphasized. The book is to be highly commended as being well calculated to give intelligent non-professional readers a clear account of the teachings of modern pathology.

Food and Feeding in Health and Disease. A Manual of Practical Dietetics. By Chalmers Watson, M.D., F.R.C.P.E., Assistant Physician, Royal Infirmary, Edinburgh. Second Edition. Cloth. Price, $5 net. Pp. 638. New York: William Wood & Co., 1913.

What was said regarding the first edition of this book might be repeated in reviewing the second edition. As the author says, he gives less attention to the chemical composition and heat values of food than to its influence on the digestive tract. In other words, the book deals more with the practical than with the academic phases of its subject-matter. As such, it will appeal to those who want a comprehensive handbook on foods and feeding, rather than a highly technical treatise on the science of dietetics.

Miscellany

Tuberculins and Tuberculosis Antiserums

This is the subject of a report prepared by a committee of the Muskogee County (Okla.) Medical Society and published in the *Journal of the Oklahoma State Medical Association* for January, 1914. The committee, which was created in October, 1913, reviews the history of Koch's tuberculin and notes that the remedy, which at one time had fallen almost into disuse, and even now does not seem to be growing in favor, is still used by some excellent men. Of the scores of biologic tuberculosis remedies that have followed Koch's pioneer work, each has had as its advocates one or more men of prominence, but so soon as it has attracted to itself the searching light of science, it has been found unable to meet its author's claims. The numerous serums, such as those of Maragliano and Marmorek, have not established themselves in the confidence of the medical profession.

The Friedmann "cure" is considered in the following words:

> We must apologize for even mentioning the Friedmann "cure," which has been declared by the general consensus of capable and unprejudiced observers to be worthless, and possibly harmful. Perhaps no other preparation with so little merit has ever been so sensationally advertised in the United States. It scarcely caused a ripple of interest in Germany, except as another illustration of the credulity and gullibility of Americans. The most unkindest cut of all was contained in a letter of the Berlin correspondent of THE JOURNAL of the American Medical Association, wherein he comments on the prevailing opinion among the Germans that American physicians are faddists and rainbow chasers, the opinion being abundantly confirmed by their reception of the Friedmann "cure." Now the truth is that the medical men of our country never looked on this preparation with other than a skeptical tolerance, which later changed to an active antagonism when it became apparent that Friedmann himself was here for the purpose of exploiting a tuberculin for which he had been scarcely able to obtain the barest recognition in his fatherland. The lay press is preeminently responsible for this monumental hoax and swindle on the American people—the lay press, aided and abetted by the attitude of many otherwise intelligent and responsible citizens. When the Friedmann sensation was at its height it was not uncommon to see expressions in the press and even hear them from those whom we know to be friends of our profession, to the effect that the doctors were fighting the Friedmann treatment because they were jealous of it. It is discouraging to realize the light in which we are held by the laity at large. Rascals there are among us, without doubt; but, on the other hand, medicine counts among its devotees many profound thinkers and self-sacrificing philanthropists. The majority of physicians have probably adopted their calling for two principal reasons: first, that they may earn a livelihood, and, secondly, that they may devote themselves unselfishly to a high calling. Were the first the only reason, few of us would be here this evening. We would be imbibing at the breast of a more lucrative occupation, and one less fraught with distressing experiences, anxiety, sleepless nights, and premature gray hairs. There is not one of us but would gladly welcome any remedy that would add to his efficiency against our mighty foe, the great white plague. We would not ask whether its originator were quack or sage, *friend* or foe, rival or coworker, so that we might hurry away to carry health to blighted homes and restore light to those that sorrow. But we consider it equally our duty to fight fraud and to resist the plundering of unfortunates. It is to be hoped that the deplorable Friedmann episode has at least had some effect in convincing the laity of the disinterested attitude of the great mass of our profession toward these remedies.
>
> The principle of the Friedmann vaccine, the attenuation of the tubercle bacillus by passage through cold blooded animals, is not a new one. It was tried out by laboratory workers years ago. It was not used clinically because previous investigators had feared to experiment along this line on human beings. It has been well established that a culture that has become avirulent by repeated transmission through cold blooded animals, as well as by treatment with heat or chemicals or other methods familiar to bacteriologists, may unexpectedly reestablish its virulence and prove fatal to laboratory animals. There is no reason to believe that Friedmann has been able to provide against this contingency in human beings.

The following account is given of Piorkowski's vaccine:

> Recently Piorkowski has been investigating clinically a turtle tuberculin from which he claims to have had some very encouraging results. As to how this differs from the Friedmann preparation or in what respects it is superior to it, we are unable to secure definite information. Without at all desiring to impeach Piorkowski's motives, we will note that at present there is an effort to exploit this preparation in a way that cannot but prove very prejudicial to it in the eyes of sagacious men. The campaign of publicity followed immediately on the heels of an article of Beattie and Myers, which was noteworthy neither for the excellence of its English nor its scientific accuracy.
>
> It is to be presumed that these attempts at exploitation are not sanctioned by Piorkowski himself. He would scarcely authorize the putting on the market, especially in such a sensational way, of a vaccine of which he himself has been quoted in a laudatory article as saying, in substance, that many thousands of cases must yet be treated before we can come to a final conclusion as to the value of the remedy. Nor is it likely that it would find a very large sale at $7.50 per c.c., were this honest estimate of its originator given the same publicity as the flattering advertisements. We must further remember that Fritz Meyer, who earlier was enthusiastic over the Piorkowski vaccine, stated before the Berlin Medical Society in June, 1913, that he had never seen a case of severe tuberculosis really improved by Piorkowski's vaccine.

A conservative estimate is given of von Ruck's preparation with a reference to the unfavorable findings of Cummins. The report concludes as follows:

> 1. There is a wide difference of opinion among those in a position to know as to the value of any specific treatment for tuberculosis, some affirming that, judiciously used, tuberculin exercises a valuable curative effect, others denying any superiority in results from the use of tuberculin over those obtained when dependence is had on hygienic measures alone.
> 2. Of those who employ tuberculin the vast majority still cling to Koch's preparation, either in its original, or in a slightly modified form.
> 3. Of those who employ tuberculin, the consensus of opinion is that the use of the remedy should be restricted to institutions where the patient can be kept under close supervision and control.
> 4. It is possible that some preparation now obscure may prove to be the long hoped for specific, or that future investigations may find such. While we should guard against unjust condemnation of even the least promising of therapeutic agents, at the same time we should be slow to give our sanction to any one of a class of products which has been made the means of so much financial piracy and has entailed such untold misery of mind and body on a multitude of unfortunates.

Number of Insane in Prussian Asylums.—There is a steady increase. *In* 1911 *there were* 132,982 (73,953 males and 59,029 females) as compared with 127,914 in 1910, 125,181 in 1909, 113,318 in 1907 and 73,955 in 1901. In 1911 there was an increase of 5,068, or 3.9 per cent., and in ten years the number has risen by 59,027 or quite 80 per cent. This increase has raised the question now so much discussed whether the figures indicate an actual increase or whether the rise is only apparent. Many alienists are of the latter opinion, and indicate as reasons for it the more exact registration of patients, the increase in asylums, the lessened dread of asylum life, the accumulation of chronic cases and the longer period of life of asylum inmates as the result of improvement in the sanitary conditions, the lesser mortality, the readmissions in various asylums, the greater attention given to mental diseases, etc. While as a general statement these reasons cannot be denied, still there is no question that modern civilization with its hurry and stress, the greater amount of intellectual exertion, stronger excitement, the misuse of alcoholic and narcotic drugs has as a result more mental disease than was formerly the case. If we take into consideration nervous diseases, morphin addiction, alcoholism, etc., the number of those cared for during the year of 1911 amounted to 147,143, of whom 55,390 were admitted during the course of the year. Among them were 3,004 persons under 16 years of age, 12,252 with hereditary taint, and 9,274 drunkards. Among the latter were 683 women.

Treatment of Infantile Dyspepsia by Sweetened Milk.—At one of the last sessions of the Académie des Sciences, Dr. Variot, physician to the hospice des Enfants Assistés de Paris, reported the good results that sweetened milk had given in infantile dyspepsia. He made the discovery by accident. A baby which had vomited all the milk given it from its birth was given sweetened condensed milk and much surprise was evinced in observing that the vomiting was stopped. In order to find if this was a mere coincidence or if condensed milk was the cause of this improvement, the sweetened condensed milk was tried on a number of dyspeptic and vomiting infants. The vomiting which had hitherto resisted all therapeutic means, including sodium citrate, decreased rapidly in number and frequency and disappeared completely at the end of a few days. Often the vomiting ceased on the very day or the day after the first feeding was given and sometimes immediately. Dr. Longeville, who devoted his inaugural thesis to this subject, believes that this remarkable result is not due to the mere condensation of the milk, for when condensed unsweetened milk was used the little patients continued to vomit. Moreover, when the sweetened condensed milk was replaced by unsweetened condensed milk, vomiting reappeared. Variot and Longevialle experimented by giving to vomiting dyspeptics a milk containing a high proportion of saccharose (10 per cent., that is to say, about the same quantity as unsweetened condensed milk); the results were the same as given by sweetened condensed milk. Of course, sweetened milk could not be employed in the regular feeding of infants, the proportion of sugar added being too large. The sweetened milk is a medicinal food, which can be used only temporarily. It is, however, capable of giving excellent service, for not only does it cause the disappearance of vomiting but it also regulates the digestion. Longevialle has seen infants who were much under weight, or whose weight had remained stationary for months, increase rapidly in weight and height.

Who Discovered Morphin?—The discovery of morphin is generally attributed to Sertürner according to an article by M. L.-G. Toraude just published in the last number of the *Bulletin des sciences pharmacologiques.* This discovery, like that of iodin, the centenary of which was recently celebrated at Dijon (The Journal, Dec. 6, 1913, p. 2080) was due to Courtois. In Dec. 24, 1804, Séguin, in whose laboratory Courtois was studying opium, placed before the Académie des Sciences a memoir in which his collaborator showed that from this opium he had isolated a crystallized body with alkaline reactions, capable of forming salts by combining with acids. This paper did not appear in the *Annales de chimie* until ten years later, but Courtois' lack of confidence in himself and the meagerness of his studies is a good excuse for this exaggerated modesty. This prevented him from being clear and decisive enough in his statements; he hesitated and made reservations with regard to the discovery. In 1817 Sertürner was bolder and reaped the glory that Courtois should have had.

Medicolegal

Validity of Statute Providing for Revocation of Licenses of Physicians Obtaining Fees on Representations that Manifestly Incurable Diseases Can Be Permanently Cured

(Graeb vs. State Board of Medical Examiners (Colo.), 135 Pac. R. 776)

The Supreme Court of Colorado holds unconstitutional the provision of the statute of that state authorizing the State Medical Board to revoke the license of a physician on the ground of "obtaining a fee on the representation that a manifestly incurable disease can be permanently cured." The court says that it could not enter into the question of the regularity of the trial of Dr. Graeb, before the board, or the sufficiency of the proof in the case, in which he had been charged with having obtained a fee on the representation that a manifestly incurable disease could be cured, by soliciting, demanding and receiving a fee and fees, on the specific representation that he could permanently cure one Shields of the disease known as consumption, of which the said Shields died. The whole question before the court hinged on what is, or whether there is, a distinctly "manifestly incurable disease." In other words, is this term sufficiently definite and specific as to constitute such an offense against the public morals and public welfare, as may be sustained by the courts, as being sufficient to justify the action of the medical board in this case? It will be observed that no disease is named in the statute as being manifestly incurable.

It was substantially admitted by counsel for the board that the statute would not be valid if construed to have reference to a disease manifestly incurable *per se,* or in itself, but it was contended that the court should construe the statute to have reference to any disease whatsoever with which the patient may be afflicted and of which disease he is in a manifestly incurable condition. But this position is not tenable. If the statute had intended a manifestly incurable person, or a manifestly incurable diseased condition, it would doubtless have so recited. The language is a "manifestly incurable disease." Clearly the descriptive words "manifestly" and "incurable" apply to the disease and not to the person or the condition of the person afflicted with the disease. If there is no disease known and understood to be manifestly incurable, then the statute states no offense in that particular, and the board was without jurisdiction in the premises.

Dr. Graeb in the complaint was charged with receiving the fee on the representation that he could cure the manifestly incurable disease, consumption, with which disease the patient at the time was afflicted. Counsel for the board said: "It is true that consumption is not a manifestly incurable disease in itself." Indeed, it was not contended that any disease is manifestly incurable, but, on the contrary, counsel for the board said: "The statutory provision does not proceed on the assumption that any disease by name, as such, is incurable, for a specific disease that is incurable to-day may be curable to-morrow through the advancement of medical science; but it proceeds on the undeniable fact, everywhere accepted, that diseased conditions do become 'manifestly incurable.'"

If, then, the State Board of Medical Examiners admit that neither consumption, the disease referred to in the complaint, nor any other disease is manifestly incurable, the court must hold as a matter of law that the statute, in so far as it is herein considered, is void because of insufficiency and uncertainty.

The only case cited by counsel for the board as tending to sustain the contention that the statute is not void for indefiniteness and uncertainty and considering anything like a similar statute was *Board vs. McCrary,* 95 Ark. 511. The statute considered in that case contained the words "chronic and incurable," which the present court regarded as different from and more definite than the words of the statute involved in this case.

It may be admitted that if Dr. Graeb was of the opinion that Shields' condition was incurable and so believed, and that having such opinion and belief he obtained from Shields a fee on the representation and promise that he (Graeb) could cure him permanently, such act on the part of Graeb would constitute such moral turpitude as might well furnish sufficient ground to deprive him of his license if there was a statute so providing. But the court has studied the statute in vain for any ground on which any such charge may be reasonably included and on which the board may revoke a medical license. The statute has omitted all such provisions as "dishonorable conduct" or such other similar causes as are common in like statutes and which have been sustained by the courts.

The statute is the sole source of the authority of the board and it assigns certain specified acts and conduct as may justify the revocation of a license. Yet it will be noted that even the commission of a crime involving moral turpitude is not a sufficient basis for revocation, but there must first be a conviction. Thus moral turpitude, except in case of conviction is eliminated as a basis for revocation under the statute. Quite clearly the causes designated in the statute are exclusive, and the maxim, "The expression of one thing is the exclusion of another," applies.

But, if the court were to concede the contention that the statute relates to the condition of the patient, and not to the disease with which he may be afflicted, when would the question of curability cease to be one of opinion and become a manifest fact? The court may concede that physicians of skill and experience can form a well-grounded opinion as to the question of curability, but of necessity this can be of no greater force than that of opinion and conclusion. Manifestation is specific demonstration to the eye, clear alike to all, skilled or unskilled. Then at what point short of death may we reasonably say that the ultimate result of such a disease ceases to be a question of opinion and becomes a manifest fact? The court is not willing to sanction a rule for punishment because of difference or mistake in opinion, or to agree that those of a skilled class may be penalized for an opinion differing from that of their fellows. If so, where is the court to draw the line of such difference, and who may be safely trusted to render judgment as between them? The court cannot concede the infallibility of man, nor deny the providence of God. If, then, it should adopt the reasoning of counsel for the board, the provision of the statute still remains too indefinite and uncertain to form the basis of a judgment for the revocation of a physician's license.

The opinion of the court was prepared by Justice Scott, with whom concurred Chief Justice Musser and Justices Garrigues and White.

In a dissenting opinion, concurred in by Justices Hill and Bailey, Justice Gabbert says: "The police power of government is inherent in every sovereignty. It is that power vested in the legislature which may be exercised by the enactment of laws, the purpose of which is to protect and promote the public welfare. That such is the purpose of the clause of the statute under consideration, and that its enforcement will protect the public, there can be no question. The majority opinion, however, decides that it does not for the reason it cannot be said there is any disease known and understood to be manifestly incurable. This is too narrow a construction.

"When is a disease manifestly incurable? Clearly when it is evident it has reached the stage that it cannot be made to yield to medical treatment. That is what laymen, as well as the medical profession, understand from the expression 'a manifestly incurable disease.' The intent of the law is to be considered in its interpretation, and, in ascertaining such intent, the evil against which it is directed must be considered. It is common knowledge that one suffering from disease can easily and readily be imposed on by those who, by reason of the fact that they have obtained a license to practice medicine, are presumed to possess that degree of skill in the treatment of disease which will enable them to accomplish that which they represent they can.

"The object of the statute is to prevent what would be nothing less than extortion by members of the medical profession, obtaining money from persons or the relatives and friends of those suffering from disease by promising a cure when it is apparent that the patient is beyond the reach of medical science. Such being the object of the statute, the words employed to express it should not be given such a narrow construction as will result in destroying its beneficent purpose, when from such language, and the general understanding of what it means, it is apparent that the legislature intended to prevent the helpless ill being imposed on by the promises of a cure when it was evident their condition was such that it could not be accomplished."

Duties of County Health Officers—Power of County Boards of Health to Employ Assistants in Cases of Epidemic

(Breckenridge County vs. McDonald (Ky.), 150 S. W. R. 549)

The Court of Appeals of Kentucky affirms a judgment in favor of Dr. McDonald for $540 for fifty-four days' services rendered during an epidemic of small-pox. He was employed by the county board of health to carry out the recommendations included in a report of a representative of the state board of health. The county defended on the theory that McDonald was employed by the county board of health to take general charge of the small-pox epidemic, and that the services rendered by him constituted the same service that was incumbent on the regularly elected health officer, a Dr. Kincheloe, whose annual salary as county health officer and secretary of the county board of health the latter had by proper resolution fixed at $75, and that neither the county board of health nor the fiscal court had the right to employ or pay a substitute to do the work of the county health officer.

The circuit judge in his findings of fact concluded that it was not the duty of the county health officer to administer treatment to patients suffering with contagious diseases, but that it was his duty only, under the statute, to take general superintendence of all contagious diseases and to institute quarantine and fumigate premises; and that the county board of health had power, under the law, to employ another physician to personally administer the treatment to patients. The proof further showed that by reason of the character of the disease, and the location of the patients at long distances from Hardinsburg, and from each other, it was impossible for the county health officer to give them the requisite personal attention without abandoning his home and practice. Some of these patients were located as far as seventeen miles or more from Hardinsburg. Dr. Kincheloe, however, not only consulted daily with Dr. McDonald by telephone, but he made three visits to Cloverport by way of supervision, spending the entire day there on each visit.

The whole question, the Court of Appeals says, resolved itself into this proposition: Can the county board of health employ agents or assistants for the health officer for the purpose of eradicating an epidemic at a distant point in the county, where the circumstances of location and the nature of the disease are such that the county health officer could not be expected to give his personal attention thereto in the ordinary course of his business? The court thinks that there can be no doubt of the right of the board so to contract.

The county relied on *Hickman vs. McMorris*, 149 Ky. 1, 147 S. W. 768, as denying that right. A careful reading of the opinion in that case shows, however, that it was not at all controlling in this case. In the McMorris case the county board of health had regularly appointed Dr. Scarborough as health officer; and, he having declined to discharge the duties of his office, the county board of health employed Dr. McMorris to perform the same duties, supervisory or otherwise, that the law imposed on Dr. Scarborough, and thus placed the county in the attitude of paying two men for precisely the same service. Under that state of case this court properly held that there could be but one county health office; it did not hold that the board could not employ the necessary assistants to enable the board and its health officer to protect the public health in times of epidemic. The contention of the county, if sustained, would forbid the board of health from employing but one physician in any case, and regardless of the necessities of the case or the amount of work to be done. In this instance Dr. McDonald at one time had as many as thirty-six cases in his locality which required his daily personal attention. It was impossible for Dr. Kincheloe to do this work and supervise the general health affairs of the county at the same time, and the court does not believe the statute contemplated that he should have done so.

The statute, in requiring the county health officer "to see that the prescribed rules and regulations are enforced," does not necessarily contemplate that he shall personally do the work. On the contrary, it contemplates rather a medical supervisory service over the employees and assistants of the board.

It is clear that the ordinary duties of the county health officer, for which he is paid a yearly salary, are largely executive and supervisory in seeing that the rules and regulations provided by law, and the rules and regulations of the state board of health, are enforced. As was well said by the chancellor, it is his duty under the statute to take general superintendence of all contagious diseases and to institute quarantine and fumigate premises, and to carry out these general purposes the county board of health has power, under the law, to employ such other physicians and nurses, guards and attendants as may be necessary to administer treatment and stamp out the disease. If there should be any doubt about the application of the foregoing rule as a general proposition, certainly there can be no doubt of its application in this case, since the treatment was not only widely extended but had to be administered at points distant from the county-seat in which the county health officer resided. His compensation was merely nominal and clearly did not contemplate that he should render the extraordinary services required in this case.

Society Proceedings

SOUTHERN SURGICAL ASSOCIATION

Twenty-Sixth Annual Meeting, held at Atlanta, Ga., Dec. 16-18, 1913

(Continued from page 328)

Treatment of Trigeminal Neuralgia by Deep Intraneural Injection for Anesthetic and Therapeutic Purposes

DR. RUDOLPH MATAS, New Orleans: Since the introduction of intraneural injections of osmic acid by Neuber, and especially of alcohol by Schlosser in 1907, I have devoted special attention to the technic of injecting the nerve-trunks for the relief of tic douloureux. More recently, however, I have gone a step further by attacking the gasserian ganglion itself. In the hands of an expert, the anesthesia of the trunks of the trigeminus at the basal foramina, more particularly the second and third divisions, and the gasserian ganglion itself, is a perfectly feasible and practical procedure which will render decided service in the surgery of the face. I will also permit of a satisfactory, safe and certain relief of trigeminal neuralgia especially when the exact localization of the nerve or the ganglion is determined by obtaining a complete and demonstrable anesthesia before the alcohol injection is made.

Cholecystectomy versus Cholecystostomy

DR. GEORGE W. CRILE, Cleveland: Considering all the consequences of infection, cholecystectomy shows a morbidity and a mortality lower than cholecystostomy. The clinical results of cholecystectomy are good, while in unsuitable cases cholecystostomy is followed by recurrent cholecystitis. I have seen no adverse effects from cholecystectomy, provided that the division is made at the beginning of the cystic duct, that no gall-bladder tissue is left, and that the division does not at all encroach on the common duct. If acute infection is present, then in most cases cholecystostomy should be first performed, followed if required by a later cholecystectomy. If the gall-bladder and the cystic duct are approximately normal, then the gall-bladder is left, cholecystostomy being the operation of choice. If the gall-bladder is thick, contains much scar tissue, is shrunken, shows chronic infection of the musculature and is much impaired, if the cystic duct is partially or completely strictured, or if a stone is impacted in the duct, then cholecystectomy is made.

Infraction of the Second Metatarsal Bone

DR. ALBERT H. FREIBERG, Cincinnati: I have had six cases of pain at the metatarsophalangeal joint of the second toe in which roentgenoscopy showed that there had been an infraction of the distal end of the second metatarsal bone. In three of the cases there were loose bodies in the joint, and in two of these cases they had to be removed in order to give relief. I saw no case less than four weeks after the injury, and in two cases there was no recollection of the injury. The trauma was always a slight one, occurring at tennis in three of the cases and consisting merely of a false step.

Aside from the roentgenogram, the diagnostic features are, the traumatic origin, thickening and marked tenderness of the second metatarsophalangeal joint and grating on passive movement if loose bodies are present. The treatment is purely mechanical save when loose bodies indicate arthrotomy for their removal, because of either their size or their number.

Open Treatment of Fractures

DR. GEORGE A. HENDON, Louisville, Ky.: The indications for the use of the Lane plate are as follows: (1) fractures that cannot be reduced by ordinary manipulations; (2) fractures that are difficult to maintain in reduction; (3) delayed union; (4) when good cosmetic effects are especially desirable, and (5) fractures communicating with a joint in

Fracture of the Neck of the Femur

DR. JAMES E. MOORE, Minneapolis: The indications in treatment of fracture of the neck of the femur are the same as in other fractures, namely, to bring the fragments into apposition and hold them there. This renders the capsule of the joint taut, and brings the floating short fragment into contact with the longer one. This side pull is brought to bear on the inner side of the upper end of the thigh by means of weight and pulley, the amount of weight being about one-third of that at the foot of the bed. Whitman's method of extreme abduction and retention by plaster of Paris will secure bony union, and is undoubtedly the best method for the treatment of children, but it is neither so comfortable nor so convenient as the "anatomic" method for adults.

Open Operation for Fractures

DR. FRANK MARTIN, Baltimore: Every known method should be made use of for the correction of fractures without operation, and only in failure to obtain good results after every good method has been tried are we justified in employing the open operation. The chief indications for the open operation are: If, after repeated attempts, the bone cannot be placed in apposition or cannot be maintained in apposition, the open operation should be resorted to. If, after reduction of fractures of long bones, no crepitus can be elicited, interposed soft parts should be suspected and the operation resorted to in order to prevent a delayed non-union. All open fractures as a rule should be cleansed, fixed, and if necessary drained. All cases of delayed non-union and all cases of vicious union should be subjected to immediate operation; no efforts at reduction without operation should be employed.

Diagnosis and Surgical Technic of Acute Abdominal Conditions

DR. JOHN YOUNG BROWN, St. Louis, considered at length gunshot and stab wounds of the abdomen, injuries to abdominal viscera, resulting from severe abdominal contusions and acute intestinal obstruction. The surgical treatment of gunshot and stab wounds of the abdomen was considered under four heads: preparation and examination of patients, method of locating injury to peritoneal viscera, repair of such injuries, and after-treatment. It has been his invariable custom to drain all gunshot and stab cases in which there was extensive soiling of the peritoneal cavity and severe hemorrhage existed. The drainage is accomplished by means of a glass tube introduced through a stab wound above the pubis and placed at the most dependent portion of the vesicorectal pouch.

Epithelial Hyperplasia in the Breast

DR. WILLIAM CARPENTER MACCARTY, Rochester, Minn.: The conditions which are associated with classical signs of carcinoma should be treated radically. The doubtful cases in women near or over 35 years of age should have the entire mammary gland removed for immediate examination. If primary or secondary hyperplasia be present nothing more should be done; if tertiary hyperplasia be present a radical operation should be performed. In doubtful cases in women near or under 35 years of age a wide section of the mammary gland, including the pathologic conditions, should be removed for examination. If primary hyperplasia be present nothing more should be done. If secondary hyperplasia be present the rest of the mammary gland should be removed, and if tertiary hyperplasia be present the radical operation should be accomplished.

This plan avoids incision of tumors. It removes the possibility of unnecessary radical operations and their physical and psychic embarrassment. It provides for a scientific means of determining more accurately the stage at which cancer may be cured by surgical operations and the extent of the operation which is necessary to effect such a cure. In the experience of the Mayo clinic the removal of the mammary gland preceding an immediate radical operation has not been associated with earlier recurrence than has been found after a primary radical operation.

WESTERN SURGICAL ASSOCIATION

Twenty-Third Annual Meeting, held at St. Louis, Dec. 19-20, 1918

(Continued from page 326)

Congenital Pyloric Stenosis

Dr. Roland Hill, St. Louis: The operation best adapted to these cases is posterior gastro-enterostomy. I have operated in ten cases; five patients recovered and five died. One of the five deaths was due to a kink, and the other four to complications existing at the time of operation. I performed a successful operation on a premature child 5 weeks old that weighed only 3 pounds and 15 ounces. This child gained 3 ounces in the first two weeks, 4½ ounces in the third week; 12½ ounces in the fourth week; 1 pound the sixth week, and still continues to gain at the rate of about 2 ounces a day. This is apparently the smallest child on record to recover after operation for this disease.

Ulcer of the Stomach in Children before Puberty

Dr. Charles D. Lockwood, Pasadena, Cal.: Ulcer of the stomach in children is relatively rare, but is probably much more frequent than heretofore believed. Many obscure abdominal conditions in children may be due to unrecognized ulcers. The rarity of ulcer in children is explained by the position of the child's stomach, permitting rapid emptying, the small amount of hydrochloric acid present and the good motility. The factors favoring ulcer are malnutrition, tuberculosis, burns, local injuries, leukemia, septicemia, anemia and chlorosis in young girls and follicular gastritis. Ulcers in children are more often superficial erosions. The typical funnel-shaped, deep ulcer found in adults is rare; when present, it is not so often found in the pyloric region and perforation is common. Perforation has been reported most often through the posterior wall, through the lesser curvature near the cardia and through the greater curvature into the pancreas, as in my own case.

Gastric ulcer should always be thought of in children with abdominal symptoms. Pain in the epigastrium, hematemesis and bloody stools are pathognomonic. Diagnosis must be confirmed by microscopic examination of stomach contents and stools for concealed blood. Appendicitis is most often confused with ulcer. In my case, palpation of the epigastric region during a paroxysm of pain first suggested ulcer. Gas could be felt to gurgle through the pylorus, followed by relaxation and relief of pain. This is believed to be an important diagnostic sign.

Removal of the Appendix in All Cases of Appendicitis with Localized Abscess

Dr. Van Buren Knott, Sioux City, Iowa: I advocate the removal of the appendix at the first operation in every case of appendicitis with localized abscess. I have a series of 501 consecutive operations for appendicitis with localized abscess, in every one of which the appendix was removed at the first operation. In this series there occurred six deaths. There was no death from peritonitis. In my own hands the mortality of operations for appendicitis with localized abscess has by this method been reduced from 8 to 1.2 per cent. In the hands of men who are qualified to operate in acute suppurative conditions within the abdomen, not only will mortality be lessened, but also convalescence will be shortened and the tendency to postoperative sequelae much diminished by the invariable employment of the method.

Sarcoma of Ovary

Dr. Miles F. Porter, Fort Wayne, Ind.: Averaging the percentages of sixteen observers covering over 3,000 cases of ovarian tumor, we find the percentage of sarcoma to all other tumors to be 5.08 per cent. About 20 per cent. of all ovarian tumors are malignant and about 5 per cent. are sarcomas; 50 per cent. of ovarian tumors occurring in patients under 5 years of age are sarcoma. Contrary to the rule, sarcoma of the ovary frequently involves both organs. This double involvement occurs in about 20 per cent. of the cases. Sarcoma is especially likely to occur in the two extremes of life. In my three cases, the youngest patient was 10 and the oldest 62 years of age. The diagnosis is seldom made save at operation or postmortem. Pain is a prominent symptom in more than a third of the cases. Disturbances of menstruation are more common in malignant than in non-malignant tumors. Especially is this true of amenorrhea. The mortality of the operation is much higher in children than in adults. The ultimate prognosis seems the best in fibrosarcoma. A permanent cure can be expected in about 10 per cent. of all cases. Even in desperate cases, the results of the operation are sometimes surprising.

Non-Papillary Benign Tumors of the Bladder

Dr. E. S. Judd, Rochester, Minn.: Out of 164 neoplasms of the bladder operated on in the Mayo clinic, two were of the non-papillary benign type, springing from the muscular layer of the bladder. In a review of the literature, I find thirty similar cases previously reported. In most of the reported cases, bleeding was the first and most marked symptom, coming apparently from the congested mucous membrane of the entire bladder, but especially that covering the tumor. These muscular tumors extend into the bladder and outward into the peritoneal cavity. The point of origin of our two was close to the meatus of the urethra. The tumors were pedunculated and were removed suprapubically. The patients made uneventful recoveries and have been well six and one and three-fourths years, respectively. Pathologically, the tumors were covered by stratified mucous membrane similar to the mucosa of the bladder. Their appearance throughout was that of uterine myomas. They were composed of smooth muscle-fibers and fibrous connective tissue.

Conservative Operative Treatment of Long-Standing Inversion of the Uterus

Dr. H. S. Crossen, St. Louis: Complete division of the anterior uterine wall and cervix (Spinelli, 1900), is the most satisfactory method. The advantages of the method are as follows: Being vaginal it minimizes the amount of peritoneal contamination. As the reposition is accomplished by incision, there is not the bruising and perforation of the friable uterine wall, which has so often accompanied attempted reposition by dilatation of the constriction ring. Division of the anterior uterine wall is preferable to division of the posterior wall, because the work is thus more easily and accurately accomplished. The anterior uterine wall and anterior fornix lie toward the operator, and are therefore less deeply situated and more easily reached. When the operation is anterior, the bladder may be lifted away, giving a wide space for investigation of the inversion-funnel and of the various pelvic structures, and also more room for the operative manipulations of incision, reposition and suturing. If there is a marked backward tendency, effective forward fastening of the uterus may be carried out through the anterior incision. A suture line on the posterior surface of the uterine wall is more likely to form troublesome adhesions—to the intestines, leading to obstruction, or to the posterior pelvic wall, leading to adherent retrodisplacement. The points in favor of the posterior incision are that it eliminates the extra opening for drainage and that the sacro-uterine ligaments may be more conveniently shortened; but these minor advantages of the posterior incision are outweighed by the more important advantages of the anterior incision.

Heat in Cancer

Dr. J. F. Percy, Galesburg, Ill.: It is logical that there may be hope for the eradication of cancerous growths by attacking them through their vulnerability to heat. The penetration of heat by my method can be definitely determined and regulated. Its applicability has almost no limitations when the malignant process is at all accessible. The required apparatus is not expensive and is easily portable. The method consists of the application of heat from an electrocautery accurately controlled by a rheostat, and applied to the affected tissues. Heat and not cauterization is the object to be attained.

NEW YORK NEUROLOGICAL SOCIETY

Stated Meeting held Dec. 2, 1913

The President, Dr. Smith Ely Jelliffe, in the Chair

A Case of Subcortical Visual Aphasia

Dr. C. C. Beling, Newark, N. J.: The patient, a man aged 62, had been a schoolteacher for over forty years. Except for an attack of inflammatory rheumatism twelve years ago, he had always enjoyed good health. There was no venereal history. Feb. 23, 1913, he first noticed some difficulty in reading his morning paper, and on the following morning he could not read at all. When I first saw him, February 28, he complained of a feeling of constriction in the left temporofrontal region, together with a failure of vision and inability to read. The pupils were regular and of equal size, and reacted normally. The fundi showed evidence only of changes due to myopia. Color recognition was very much impaired, and it was almost impossible for the patient to distinguish one color from another. There was a right homonymous hemianopsia.

The patient's vocabulary was much more limited than normal, especially without distinct conscious effort. Pronunciation and speech were fluent; words or syllables were not displaced and the interpretation of nouns and verbs was accurate. He could write spontaneously, but writing meant nothing to him. He read many letters incorrectly. He did not understand written questions or commands that were shown to him, yet their letters and forms were distinct to him, but not their names and sounds. He could repeat the alphabet readily. He was unable to copy from printed to written letters, but he could copy from print to print and with difficulty from writing to writing. He could write from dictation words that he heard and could repeat them correctly. Objects seen he could name only with the greatest difficulty, and by a process of roundabout association. He was unable to estimate distances correctly. There were no visual hallucinations.

The patient had a systolic murmur at the apex, with marked accentuation of the second aortic sound. The blood-pressure was 250 mm.; pulse, 60. The reflexes of the upper extremity were active. The patellar reflexes were exaggerated, especially that on the right side. There were no Babinski, no ankle-clonus, and no rectal or vesical involvement. There were no sensory disturbances to touch, temperature or pain. The examination was otherwise negative. The patient stated that he had a subjective loss of equilibrium. There were no evidences of ataxia. The diagnosis in this case was subcortical visual aphasia (pure word-blindness or alexia), associated with right homonymous hemianopsia and hemiachromatopsia, indicating a subcortical lesion beneath the left angular gyrus, probably hemorrhagic in nature, cutting off the afferent visual impulses from both half vision centers to the visual word center, and to some extent implicating the optic radiation.

DISCUSSION

Dr. L. Casamajor: During the past two years I have seen two cases of alexia, without agraphia. One case was that of a young woman, with absolute alexia and a clear-cut hemianopsia. When I saw her again, about a year later, she had been fairly successful in reeducating herself, which she did by reading until she could understand what she read. In the other case there was a tumor of the calcarine fissure and the patient did not recover his ability to read.

Dr. William B. Noyes: I have often been told by teachers and those who observe schoolchildren, that the number of cases of alexia or freak spellers is rapidly on the increase. There are a certain number of children, apparently bright and well up in their classes in other studies, but hopelessly behind in spelling, and in their whole school life they are retarded because they can never learn to spell correctly. Such children are probably examples of developmental alexia, and are unable to distinguish between the finer points of certain letters. Memory and retention are good, but they often fail in spelling, including sometimes even the simplest words.

Wilson's Disease, Paralysis Agitans or Multiple Sclerosis?

Dr. William C. Herring and **Dr. Smith Ely Jelliffe:** The patient was a man aged 29, a telegrapher, who complained of a tremor with which he was visibly affected. In 1910 he first noticed a tremor of his left hand; this gradually became worse, affecting the function of the hand and arm. Within six months there developed a marked stiffness and apparent weakness of the arm which has grown worse. About this time the right hand and arm became similarly affected, so that in the latter part of 1911 he was unable to continue his work at the telegraph key. The tremor has become more and more violent, and the stiffness more marked and disabling. For the past two years he has also had difficulty in retaining the urine. About two years ago he noticed that the left side of his face was "drawn," and he also thought that his voice had become affected and that he found it more difficult to talk than formerly. The tremor now affected the entire body, including the head. He found it very difficult to do anything for himself, such as dressing and undressing, although he was able to walk and get about. The patient denied syphilis, but admitted four distinct attacks of gonorrhea. As a child he had had measles and diphtheria.

The tremor, coarse and of considerable amplitude, and more or less rhythmic, was not aggravated by the performance of a single act, nor did it have the character of the so-called "intention tremor." On the other hand, the performance of any more complicated maneuver, such as unlacing his shoes or buttoning his clothes, seemed to make it worse. There was no nystagmus, and the eye movements were unaffected and normal, as were the pupillary reflexes. There was a spasticity or hypertonicity of both the upper and lower extremities; the deep reflexes were sluggish and difficult to obtain, but all seemed to be present. The reflexes of the right side seemed to be slightly more active than those of the left, and this was particularly true of the patellar reflexes. No clonus was obtained. In the superficial reflexes there was a considerable difference between the two sides in the abdominal and cremasteric reflexes, that on the left side in both cases being feebler and more sluggish. The plantar reflexes were markedly different from one another, the right one being distinctly flexor and the left as distinctly extensor; both, however, were feeble and of small extent. There did not seem to be any impairment of the gait. There was no ataxia or incoordination of slowly executed movements. There was, however, a marked adiadokokinesis shown, when the patient attempted rapid symmetrical movements with both hands. The eye-grounds were normal, and there were no signs of choked disk or optic atrophy. Vision was 20/20, and there were no scotomas or interlacings of the color-fields.

The serologic examinations of the blood and spinal fluid were negative. The globulin test and leukocyte-count were normal. The pressure of the spinal fluid, however, was very low, namely, 20 mm. of mercury. The spinal fluid showed the presence of a sugar-like substance with Fehling's test. The urine showed the presence of considerable indican but was otherwise negative. There was a marked dermographia rubra, especially marked on the back. There were no gross sensory changes, and stereognosis was intact. The patient complained of occasional paresthesia and numbness of the hands.

DISCUSSION

Dr. B. Sachs: I think that the case presents an abnormal type of paralysis agitans.

Dr. Foster Kennedy: The tremor does not impress me as being similar to that of Wilson's disease. In the facial expression, however, there is a close similarity, but there is apparently lacking the instability in the patient's emotional sphere which is quite characteristic of Wilson's disease. I am inclined to agree with Dr. Sachs that the case represents an abnormal type of paralysis agitans.

Dr. I. Abrahamson: This patient has no indications of a multiple sclerosis, except a diminished abdominal reflex on one side, and a very doubtful Babinski. Pathologically, the lesion can best be placed in the midbrain, and the diagnosis should be somatic, without attempting to give the disease a name. I do not think that the picture corresponds entirely with Wilson's disease; rather, I should class it as a degenerative disease of the midbrain.

DR. WILLIAM M. LESZYNSKY: The symptoms seem to correspond more with paralysis agitans than anything else. I have seen several cases of this disease in youthful patients and recall one in particular, in which, as the man grew older, a typical paralysis agitans developed.

(To be continued)

11 Metabolism, Prevention and Successful Treatment of Rheumatoid Arthritis. (To be continued). R. Pemberton, Philadelphia.

3. **Circulatory Failure in Diphtheria.**—MacCallum reports twenty-six experiments on dogs which seem to show fairly well that the death which occurs in the height of an attack of diphtheria is not exclusively the result of direct injury to the heart, although that may play some part in the process.

4. **Bleeding in Typhoid.**—In studying the last 1,591 cases of typhoid treated in the Toronto General Hospital it appears that the mortality was 8.67 per cent. over all, but that the death-rate among those reported as having had one or more hemorrhages was 37 per cent. This latter figure is almost the same as occurred in Cruschmann's series at Leipsic, which was 38 per cent., while in Strümpell's forty-five cases of hemorrhage in typhoid it was 42.2 per cent. In the Toronto series, excluding the cases that had bleeding, the mortality of the remaining 1,464 cases was only 6.3 per cent. Rudolf cites twelve cases which show how the bleeding was followed by a more or less marked fall not only in the temperature but also in the pulse rate. They are said to be the best examples, but most of the other 115 charts of cases with bleeding showed more or less of the same thing. The improvement in the temperature and pulse curves, while often transient, in some cases lasted for days and even ushered in convalescence.

Rudolf agrees that it is difficult to explain how the good effects that may follow a hemorrhage come about. There is no doubt, however, but that it produces a profound effect on the whole bodily economy. Thus bleeding has been shown to bring about an increase in the flow of urine, to greatly increase the intake of oxygen, with proportionate raising of tissue-oxidation. It hastens the coagulation time of the blood more than does any other single agent. It produces a rapid increase in the antibodies contained in the blood. The agglutinating power of the blood is enormously raised by the bleeding. Further, in toxic conditions, such as uremia and other less-defined states, states in which there is high blood-pressure, bleeding appears in some way to lessen the toxemia, and possibly in typhoid it may have some similar effect.

Rudolf agrees with Whitehead, who two years ago, suggested that the good effects of hemorrhage in typhoid might be attained and the evil ones (associated with intestinal hemorrhage) avoided by the timely use of venesection in those cases which are not doing well on account of severe infection and toxemia. Venesection, he says, appears to be indicated in severe cases and if the removal of blood by venesection be a moderate one, say of 6 to 14 ounces, it can do no harm and may possibly be productive of great good.

6. **Auricular Fibrillation.**—A note of warning is sounded by James and Hart, namely, that in auricular fibrillation palpation of the radial pulse is a misleading guide to the determination of the condition of the circulation. The pulse deficit is a simple and useful means of following the progress of cases of auricular fibrillation, and of confirming observations on the value of various therapeutic measures, including the activity of various preparations of different drugs. The relative deficit is of value in the diagnosis of suspected cases of fibrillation. The ordinary method of estimating blood-pressure is misleading in cases of auricular fibrillation; it may with advantage be replaced by estimating the average systolic blood-pressure, which gives an approximate measure of the real systolic pressure. The administration of digitalis elevates blood-pressure in cases of auricular fibrillation.

7. **Changes Produced by Roentgen Rays in Leukemic Tissues.**—In no case of leukemia treated by Warthin by Roentgen irradiation were the conditions in the hematopoietic organs changed to a *normal condition.* The effect of the treatment is essentially degenerative and inhibitive, but the essential leukemic process goes on unchecked, although greatly modified. The treatment is, therefore, not curative. In the first stages of the treatment the leukemic tissues show great degeneration and destruction of the white-cell-forming tissues. It may completely disappear from the spleen, and the processes of white-cell formation may be so inhibited that a leukemic condition of the blood may result. After some months there arises a more undifferentiated leukoblastic tissue, particularly in the retroperitoneal hemolymph nodes and in the bone-marrow; the leukemic condition of the blood may return or it may not. With an increasing cachexia the process may be terminated by symptoms of intoxication, or by some secondary event, as hemorrhage from the necrotic spleen.

The changes in the kidney, which may be very marked (cloudy swelling, simple necrosis, and calcification), may also in part be responsible for the fatal termination. Prolonged irradiation of the hematopoietic organs in leukemia causes first a degeneration of the young and maternal cells, leading to a great decrease in the output of leukocytes, particularly in myelemia. To this destructive effect there follows a reaction in which cells of a more resistant type are formed, and the essential leukemic process remains unchecked, although altered in character.

8. **Early Excision of Cancer.**—After a most careful investigation of all the facts available from about 1,300 cases of tumors of the breast, Bloodgood formulates the following conclusions: If every woman over 25 years of age were to seek surgical advice the moment she felt a lump in the breast and the surgeon explored this lump at once, the probabilities are that the lump would prove to be benign in about 33 per cent. of cases; in the malignant cases the chances are that the tumor would be adenocarcinoma in 20 per cent. of the cases, with the probability of a cure of 100 per cent. If the lump represented the most malignant forms of cancer, the chances are 85 per cent. of a cure. Now, with the same good surgery these figures should improve as the number of early cases increases. For undoubtedly many cases of cancer subjected to operative treatment late had been distinctly benign lumps for months or even years.

9. **Acid Intoxication in Infants**—A series of cases of severe types of acid intoxication which usually terminated fatally is cited by Abt They occurred mostly in previously healthy infants at about the weaning period In most instances the infants came from healthy parents In one family two children had died from this affection The third child was similarly attacked, but recovered after a severe illness The illness usually occurs in large, robust, previously healthy infants The disease is ushered in by gastro intestinal symptoms, consisting of more or less diarrhea, and nearly always vomiting The patients are at first restless and show moderate febrile reaction during the first days of the illness, rarely exceeding 101 F Later on the temperature tends to be lower, averaging between 99 and 100 F On the second or third days there is some abdominal distention, dyspnea, with rapid respiration and an increase in pulse rate The respirations are labored, and the accessory muscles of respiration show marked activity

The liver is markedly enlarged, the edges are plump, and the surface firm The urine soon contains albumin, and hyalin and granular casts, without blood, with acetone and diacetic acid In one of Abt's cases leucin and tyrosin were also found The urine contains no sugar About the third day stupor is noted, which gradually deepens into coma The blood shows no pathologic changes, the leukocytes vary between 9,000 and 12,000 and the differential count shows no variation from normal Toward the close of the disease intestinal atony may occur As a result, no feces or gas are passed voluntarily, nor can any intestinal evacuation be induced by mechanical or therapeutic agents

Abdominal distention increases progressively and cyanosis and dyspnea are marked Unconsciousness continues, and occasionally vomiting persists until the end The reflexes are present and normal There are no symptoms of cranial nerve involvement, and usually no pulmonary complications When death takes place it usually occurs in four or five days after the onset The baby which recovered under treatment received considerable proteids in the form of casein, gelatin, soy bean flour, and the animal broths together with carbohydrates Abt assumed that the patient had an intolerance for fat, consequently carbohydrates were given in abundance in the form of cooked starch and levulose

13 **Measured Feeding for Older Children**—The diet of all improperly nourished children, and occasionally of well nursed children, Emerson maintains, should be checked up and controlled by measured feeding A preliminary forty eight hour list, kept without any suggestions from the physician, shows the quantity and kind of food habitually taken as well as the likes and dislikes of the child Changes in diet should be made gradually along lines of least resistance

The average gain on diet alone of children who are under weight should be from one half to two pounds per week If no gain is made, organic disturbances or toxic absorption should be suspected Serious errors in diet cannot be detected by asking the child about his appetite or the mother about the diet given Food must be recorded and measured in order to show how much is taken Almost invariably the overweight child is overweight because he eats too much, and the underweight child is underweight because he eats too little

Measured feeding is an important therapeutic test Emerson gives a long list of foods showing the calories in each represented by proteid, fat and carbohydrate

21 Gastric Hyperacidity F W Rolph Toronto
22 *Periosteum W E Gallie and D E Robertson, Toronto

19 **Treatment of Cholelithiasis**—While surgical procedure is frequently the best, and often the only means offering a chance of relief, Anderson states that its advocacy, based on certainty of cure and assurance of non recurrence, is not borne out by results The main object of treatment is the relief of the infection and inflammatory changes, and not merely the removal of the gall stones So long as there is no recurrence of the inflammatory attacks, there will be no attacks of gall stones Recovery not infrequently occurs under non operative treatment, especially in early and mild cases, *and particularly after first attacks*, before serious local damage has been produced by the infection Anderson insists that medical treatment should be given a fair trial in all cases in which the patient's physical condition does not warrant operation, and with the numerous patients who refuse operation In many such cases he has *seen complete* and permanent recovery from all symptoms of the disease

Medical treatment, Anderson claims, is indicated in many cases as a preliminary to operation, and in order to allow the acute infection to subside as far as possible It is indicated in all cases after operation to allow of complete subsidence of the infection and, if possible, to prevent reinfection and recurrence He suggests that we adopt the suggestion *of Naunyn and give up the term cholelithiasis and classify* these various infections of the biliary passages as cholangitis with qualifying terms such as simple, catarrhal, suppurative gangrenous, calculous, etc, according to the condition present in the particular case The non operative treatment advised by Anderson, is the Karlsbad cure or some home modification of this treatment This consists chiefly in the copious use of hot Carlsbad water or Carlsbad salts dissolved in hot water The waters *of Vichy, Ems and Neunahr have a* similar action In addition rectal injections of hot water are sometimes used The diet should be plain and unirritating, and the intervals between meals should not be too long The administration of bile salts and salicylates for their chologogic effect, and of hexamethylenamin as a biliary antiseptic, is considered to be of value

22 **The Periosteum**—The results of a general study of the *regeneration of the bone are detailed by Gallie and Robert*son Their findings agree with those of Macewen They conclude that his view that the periosteum is merely a fibrous membrane without osteogenetic function, is probably the correct one Osteogenesis appears to be solely a property of the endosteum, and appears to be as energetic in the absence as in the presence of the periosteum Even as a source of blood supply the periosteum does not seem to be of great importance, for *large areas of bone may be denuded without* any apparent effect on it There has been considerable discussion of late as to whether bone grafts should be trans*ferred with the periosteum in situ or not Gallie and Robert*son have done many experiments with small grafts, always completely denuding the bone before making the transfer, and in no case has there been any difficulty in getting the grafts to take

40. **Glycid and Acetole in Organism.**—Glycid and acetole were the substances studied by the authors in this series of experiments. They were prepared in pure form and administered to healthy animals and to fully phlorhizinized dogs. It was found that glycid is toxic. Doses of 0.3 to 0.4 gm. per kilo of body weight cause narcosis, accompanied at times by muscular twitching which is opened in the body with difficulty. Acetole is relative non-toxic. Doses of 2 gm. per kilo of body weight do not kill, but even moderate doses cause hematuria and hemoglobinuria. When given to phlorhizinized dogs either subcutaneously or by mouth, acetole causes no output of extra sugar. Some unchanged acetole may appear in the urine and so raise its total reducing power. There is an apparent rise also of the acetone bodies. The behavior of acetole in the body is explained on the basis that it disassociates into acetaldehyd and hydroxymethylene. Acetole is not a normal intermediate between substances of the formula $C_6H_{12}O_6$ and those of the formula $C_3H_6O_2$.

41. **Iodin Content of Thyroid.**—Iodin was found by Cameron to be present in the thyroids of the pigeon, alligator and frog, in amounts corresponding with the diets of these animals. It is also present in the thyroid of the dogfish. He believes that further support is therefore given to the theory that it is an invariable constituent of thyroid tissue. Iodin is absent from the ventral branchial body of the frog. The amount of iodin present in the parathyroids of the dog is of a less order of magnitude than that in the corresponding thyroids, if, indeed, the actual quantity observed be not wholly attributable to thyroid contamination. Cameron's results indicate a differentiation of function between the thyroid and parathyroid.

47. **Pancreas and Acetoacetic Acid Formation.**—Addition of pancreas extract to the blood was found by Dakin and Dudley to have no marked effect on acetoacetic acid formation in the liver from butyric acid, homogentisic acid or tyrosine.

48. **Changes in Fat during Absorption.**—Evidence is presented by Bloor of changes in fat during absorption as follows: A lowering of the melting point of high-melting point fats by the addition of an unsaturated fatty acid, probably oleic acid. The addition is proportional to the melting point of the fatty acid fed. An elevation of the melting point and lowering of iodin number of a low melting point fat (olive oil) by the addition of saturated fatty acids. Addition of "oleic acid" together with a change of melting point in a fat which consists mainly of glycerids of saturated fatty acids (cocoanut oil). Lowering of the iodin number of a fat (cod liver oil) which contains a large percentage of glycerids of highly unsaturated fatty acids. The intestine appears to have the power to modify radically the composition of the fats during absorption. The changes are apparently purposive in that they vary in kind and degree with the nature of the fat fed and also show in general a tendency toward the production of a uniform chyle fat, presumably the characteristic body fat of the animal. The observations suggest to Bloor that the mechanism serves to permit adaptive changes in the fats during absorption.

54. **Chemistry of Gluconeogenesis.**—The outcome of their experiments lead Ringer and Frankel to conclusions diametrically opposed to those of Friedman, who found that acetaldehyd on perfusion through the surviving liver gives rise to aceto-acetic acid. On giving acetaldehyd subcutaneously, however, the authors found that it has just the opposite effect.

67. **Extirpation of Bacillus Diphtheria.**—His experiments have convinced Ten Broeck that *Achlya muscaris* possesses the power of destroying *B. diphtheriae* in culture and in the throat. Throat inoculations of this fungus are usually self-limited and may require some adjustment in the way of repeated inoculations or inoculation in special areas or under special conditions to embrace all complications in the nose. It has the power of inhibiting the growth of a number of throat pathogens and seems to influence favorably membranous anginas of various origin. Its clinical use seems to be attended with no danger but after treatment with mild antiseptics is recommended to remove the fungus. It is applicable in all stages of the disease and seems to give speediest results in the early cases. There are grounds for believing that a throat in which this fungus is growing is soon shorn of its danger of contagion even if the diphtheria bacilli are still harbored. It is admirably adapted to the clinical requirements for reliable and ready use.

74. **Lumbosacral Pelvic Pain.**—The question whether lumbago is a manifestation of gout or articular rheumatism, Henry states, has little bearing on therapeutics for, in most cases, the salicyl compounds and their congeners, as well as colchicum, are not of much avail. Nevertheless, the salicyl compounds should be given a trial especially at the beginning of the attack, and they will sometimes abort it. Henry has seen excellent results from a single large dose of quinin, meaning thereby from 10 to 20 grains, administered at the onset of the affection. Fagge taught that lumbago is generally due to a hyperacid state of the urine and there are many who still hold this opinion. The indication, from this therapeutic point of view, is to make the urine alkaline as rapidly as possible with sodium or potassium bicarbonate or potassium citrate which seems to be the favorite drug for this purpose employed by the English practitioners. Henry prefers half-dram or dram doses of Rochelle salts. They may be administered every hour or two until the urine is alkaline and the bowels freely moved. The attempt to "walk it off," at its commencement, may succeed if the exercise is accompanied with free perspiration, but, in Henry's experience, those who suffer from lumbago do not perspire readily. A Turkish bath in the early stage is safer and more effective than exercise. When the affection is established, rest is imperative. Then, also, local treatment consisting of dry cups, deep massage, and the faradic current should be instituted, and if the salicyl compounds and their numerous succedanea have failed, successful resort may be had to iodin. This drug Henry has found most efficient in its combination with a vegetable protein.

80. **Venesection in Cerebral Hemorrhage.**—MacFarlane believes it is a fact beyond dispute that any patient suddenly becoming unconscious or presenting symptoms of cerebral insult with a blood-pressure of more than 200 mm. should be bled immediately. In the unusually stout person there may be some difficulty in finding easily a vein at the bend of the elbow, but in these patients there are usually in the legs varicose veins which stand out imploring to be relieved. He reports four cases. In three cases 12 ounces of blood were withdrawn; in the fourth case 3 pints were removed.

88. **Phthalein Renal Test.**—In ten cases of renal calculus studied by Caulk and Davis, this test has shown a slight delay in the time of appearance and also a slight diminution in the amount of total excretion from the calculous kidney as compared with the normal. The diminution, however, has in no case been marked, except in two cases of calculus pyonephrosis, in which instances the diseased kidney showed practically on excretion of the dye and the normal kidney put out an amount equal to that of the combined output of normal cases, showing compensatory hypertrophy of the normal kidney. They have studied fourteen cases of renal tuberculosis. The test has demonstrated greater reduction of output in cases of unilateral tuberculosis than in stone cases.

In several cases in which the urinalysis showed the quality of the urine to be practically the same from the two sides, as far as specific and urea gravity were concerned, the test showed *a marked depression on the diseased side.* In cases of double renal tuberculosis there has been quite a diminution in the amount of the dye excreted, and in none of the cases did it exceed 35 per cent. from the two sides for two hours.

In six cases of pyonephrosis, three were back of ureter strictures, two back of ureteral calculus and one a double pyonephrosis, evidently of hematogenous origin. In the cases of unilateral pyonephrosis, the pyonephrotic kidneys showed either no excretion at all or a marked diminution, with one exception, an old woman, 69 years of age, with a small stone in the lower ureter. Both sides showed about the same output, both being reduced. In the cases of unilateral disease the normal kidneys excreted an increased amount of the dye, and in no case was there any uremia following operation. In eleven cases of pyelitis there has been practically a normal time of appearance and of total excretion, and in cases of double pyelitis the two sides excreted practically the same amount of dye. Three cases of hypernephroma with metastases showed a normal time of appearance, normal amount of excretion, the two sides being equal. Two cases of floating kidney showed normal outputs. In 16 cases, in which a severe renal lesion had been previously diagnosed from the urinalysis and clinical examination, the test was below 45 per cent. in all, and below 20 per cent. in 11 of them, while the time of appearance of the dye in the urine was from eight to thirty-five minutes; the blood-pressure was high in every case. The test was made on patients who were uremic; in 3 of these the time of appearance was over one hour, and the two-hour output from 8 to 14 per cent., while in the fourth case the color did not appear for two and one-half hours. All 4 patients died within five days. Eight of the cases having kidney lesions along with other more or less important lesions, have gone to autopsy and the test has agreed perfectly with the findings, while in 3 of them the clinical examination had not revealed any kidney lesion of importance until the test was made.

89. **Primary Carcinoma of Appendix.**—Rassieur's first case he found while operating for retroversion of the uterus; the second case while making an interim operation for recurrent appendicitis. In the first instance he found a tumor on the end of the appendix ½ inch long. He removed the appendix and found that the lumen did not extend to the tip of the appendix on account of the presence of the tumor. The appendix was forwarded to the laboratory with the provisional diagnosis, inflammatory tumor of the appendix. Microscopic examination proved that the latter was a carcinoma involving all the tunics to the serosa. The adjacent Lieberkuhn glands showed a mucous enteritis. There was no other inflammatory reaction. The tumor was a yellow color on cut section. Now two years and two months have elapsed and the patient presents no signs of recurrence. When removing the appendix, Rassieur removed no more mesentery than is done in any interval case. In the second case, the appendix

was coiled cochlea-like. There were many adhesions of the meso-appendix. There was no lymphatic involvement. The tip of the appendix was tense, distended, hard and presented a bean-like enlargement ⅝ inch in diameter. The appendix was removed. On incising the appendix the small tumor looked yellow. From that Rassieur made the diagnosis of primary carcinoma. The microscopic examination showed an alveolar carcinoma with a well-developed stroma involving all the tunics to the serosa. One-half year has elapsed since the operation; the patient is very healthy and shows no signs of recurrence.

120. **Cerebrospinal Fluid and Epilepsy.**—Tests made by Gordon showed that the cerebrospinal fluid of epilepsy patients contains poisonous elements which were antagonistic to each other's blood, but not to their own. Otherwise speaking, each cerebrospinal fluid contained substances which acted specifically on another epileptic but not on the donor. Starting from this principle he selected, at first, two grave cases of epilepsy in which the ordinary treatment was of no avail. He withdrew from each 30 c.c. of cerebrospinal fluid and immediately injected subcutaneously 3 c.c. into each other's arm. Headache followed at the end of each withdrawal of fluid, but it disappeared in twenty-four and forty-eight hours. The patients were watched closely; the bromids were continued as usual. During the following three days, until the second injection, no attack occurred. During the following two weeks the patients had four injections and not a single attack occurred. On the third week, the supply of the cerebrospinal fluid became exhausted. The patients began to show recurrences. The seizures, however, were comparably milder than the original ones, and different in character. They were of the nature of petit mal. The histories of the cases detailed show that even the early results were striking. The subsequent course of the disease, the intervals between the recurrences, the nature of the latter, the freedom from attacks for weeks, the improvement in the mentality and the general health of the patient, and, finally, the discontinuance of bromids, Gordon believes, tend to show that the results from this new method of treatment are very promising.

Encouraged by the first two cases he applied the same treatment to two other cases. The last one, in a little girl, presented certain features that left no doubt of the efficacy of the method. In her case no lumbar puncture was performed so that withdrawal of fluid could not be considered as the cause of her remarkable improvement. Gordon is positive that the improvement in all probability was due to the subcutaneous injections of the cerebrospinal fluid. The four patients treated with subcutaneous injections of cerebrospinal fluid, taken for each from another epileptic, were benefited considerably. The direct effect of this procedure in Gordon's opinion was, and is unmistakable, for the reason that prior to this treatment for months and years the patients received uninterruptedly large doses of bromids and other drugs, and there was, comparatively speaking, very little or no relief. The improvement after the administration of the cerebrospinal fluid was strikingly noticeable not only with reference to the severity of the individual attacks, but also to their frequency. The intervals between the seizures were remarkably long considering their occurrence before the new treatment was instituted. Moreover, in some of the cases the nature of the attacks changed: petit mal took the place of grand mal. The mental hebetude following the epileptic seizures became here exceedingly slight. The treatment, in short, proved to be highly beneficial. No final claim is made as to the curability of epilepsy by this method.

67. **Extirpation of Bacillus Diphtheria.**—His experiments have convinced Ten Broeck that *Achlya muscaris* possesses the power of destroying *B. diphtheriae* in culture and in the throat. Throat inoculations of this fungus are usually self-limited and may require some adjustment in the way of repeated inoculations or inoculation in special areas or under special conditions to embrace all complications in the nose. It has the power of inhibiting the growth of a number of throat pathogens and seems to influence favorably membranous anginas of various origin. Its clinical use seems to be attended with no danger but after treatment with mild antiseptics is recommended to remove the fungus. It is applicable in all stages of the disease and seems to give speediest results in the early cases. There are grounds for believing that a throat in which this fungus is growing is soon shorn of its danger of contagion even if the diphtheria bacilli are still harbored. It is admirably adapted to the clinical requirements for reliable and ready use.

74. **Lumbosacral Pelvic Pain.**—The question whether lumbago is a manifestation of gout or articular rheumatism, Henry states, has little bearing on therapeutics for, in most cases, the salicyl compounds and their congeners, as well as colchicum, are not of much avail. Nevertheless, the salicyl compounds should be given a trial especially at the beginning of the attack, and they will sometimes abort it. Henry has seen excellent results from a single large dose of quinin, meaning thereby from 10 to 20 grains, administered at the onset of the affection. Fagge taught that lumbago is generally due to a hyperacid state of the urine and there are many who still hold this opinion. The indication, from this therapeutic point of view, is to make the urine alkaline as rapidly as possible with sodium or potassium bicarbonate or potassium citrate which seems to be the favorite drug for this purpose employed by the English practitioners. Henry prefers half-dram or *dram doses of Rochelle salts. They may be* administered every hour or two until the urine is alkaline and the bowels freely moved. The attempt to "walk it off," at its commencement, may succeed if the exercise is accompanied with free perspiration, but, in Henry's experience, those who suffer from lumbago do not perspire readily. A Turkish bath in the early stage is safer and more effective than exercise. When the affection is established, rest is imperative. Then, also, local treatment consisting of dry cups, deep massage, and the faradic current should be instituted, and if the salicyl compounds and their numerous succedanea have failed, successful resort may be had to iodin. This drug Henry has found most efficient in its combination with a vegetable protein.

80. **Venesection in Cerebral Hemorrhage.** — MacFarlane believes it is a fact beyond dispute that any patient suddenly becoming unconscious or presenting symptoms of cerebral insult with a blood-pressure of more than 200 mm. should be bled immediately. In the unusually stout person there may be some difficulty in finding easily a vein at the bend of the elbow, but in these patients there are usually in the legs varicose veins which stand out imploring to be relieved. He reports four cases. In three cases 12 ounces of blood were withdrawn; in the fourth case 3 pints were removed.

94 Case of Diaphragmatic Hernia. H. P. Kuhn, Kansas City.

88. **Phthalein Renal Test.**—In ten cases of renal calculus studied by Caulk and Davis, this test has shown a slight delay in the time of appearance and also a slight diminution *in the amount of total excretion from the calculous kidney* as compared with the normal. The diminution, however, has in no case been marked, except in two cases of calculus pyonephrosis, in which instances the diseased kidney showed practically on excretion of the dye and the normal kidney put out an amount equal to that of the combined output of normal cases, showing compensatory hypertrophy of the normal kidney. They have studied fourteen cases of renal tuberculosis. The test has demonstrated greater reduction of output in cases of unilateral tuberculosis than in stone cases.

In several cases in which the urinalysis showed the quality of the urine to be practically the same from the two sides, as far as specific and urea gravity were concerned, the test showed a marked depression on the diseased side. In cases of double renal tuberculosis there has been quite a diminution in the amount of the dye excreted, and in none of the cases did it exceed 35 per cent. from the two sides for two hours.

In six cases of pyonephrosis, three were back of ureter strictures, two back of ureteral calculus and one a double pyonephrosis, evidently of hematogenous origin. In the cases of unilateral pyonephrosis, the pyonephrotic kidneys showed either no excretion at all or a marked diminution, with one exception, an old woman, 69 years of age, with a small stone in the lower ureter. Both sides showed about the same output, both being reduced. In the cases of unilateral disease the normal kidneys excreted an increased amount of the *dye, and in no case was there any uremia following opera*tion. In eleven cases of pyelitis there has been practically a normal time of appearance and of total excretion, and in cases of double pyelitis the two sides excreted practically the same amount of dye. Three cases of hypernephroma with metastases showed a normal time of appearance, normal amount of excretion, the two sides being equal. Two cases of floating kidney showed normal outputs. In 16 cases, in which a severe renal lesion had been previously diagnosed from the urinalysis and clinical examination, the test was below 45 per cent. in all, and below 20 per cent. in 11 of them, while the time of appearance of the dye in the urine was from eight to thirty-five minutes; the blood-pressure was high in every case. The test was made on patients who were uremic; in 3 of these the time of appearance was over one hour, and the two-hour output from 8 to 14 per cent., while in the fourth case the color did not appear for two and one-half hours. All 4 patients died within five days. Eight of the cases having kidney lesions along with other more or less important lesions, have gone to autopsy and the test has agreed perfectly with the findings, while in 3 of them the clinical examination had not revealed any kidney lesion of importance until the test was made.

89. **Primary Carcinoma of Appendix.**—Rassieur's first case he found while operating for retroversion of the uterus; the second case while making an interim operation for recurrent appendicitis. *In the first instance he found a tumor on the* end of the appendix ½ inch long. He removed the appendix and found that the lumen did not extend to the tip of the appendix on account of the presence of the tumor. The appendix was forwarded to the laboratory with the provisional diagnosis, inflammatory tumor of the appendix. Microscopic examination proved that the latter was a carcinoma involving all the tunics to the serosa. The adjacent Lieberkuhn glands showed a mucous enteritis. There was no other inflammatory reaction. The tumor was a yellow color on cut section. Now two years and two months have elapsed and the patient presents no signs of recurrence. When removing the appendix, Rassieur removed no more mesentery than is done in any interval case. In the second case, the appendix

was coiled cochlea-like. There were many adhesions of the meso-appendix. There was no lymphatic involvement. The tip of the appendix was tense, distended, hard and presented a bean-like enlargement ⅜ inch in diameter. The appendix was removed. On incising the appendix the small tumor looked yellow. From that Rassieur made the diagnosis of primary carcinoma. The microscopic examination showed an alveolar carcinoma with a well-developed stroma involving all the tunics to the serosa. One-half year has elapsed since the operation; the patient is very healthy and shows no signs of recurrence.

120. **Cerebrospinal Fluid and Epilepsy.**—Tests made by Gordon showed that the cerebrospinal fluid of epilepsy patients contains poisonous elements which were antagonistic to each other's blood, but not to their own. Otherwise speaking, each cerebrospinal fluid contained substances which acted specifically on another epileptic but not on the donor. Starting from this principle he selected, at first, two grave cases of epilepsy in which the ordinary treatment was of no avail. He withdrew from each 30 c.c. of cerebrospinal fluid and immediately injected subcutaneously 3 c.c. into each other's arm. Headache followed at the end of each withdrawal of fluid, but it disappeared in twenty-four and forty-eight hours. The patients were watched closely; the bromids were continued as usual. During the following three days, until the second injection, no attack occurred. During the following two weeks the patients had four injections and not a single attack occurred. On the third week, the supply of the cerebrospinal fluid became exhausted. The patients began to show recurrences. The seizures, however, were comparably milder than the original ones, and different in character. They were of the nature of petit mal. The histories of the cases detailed show that even the early results were striking. The subsequent course of the disease, the intervals between the recurrences, the nature of the latter, the freedom from attacks for weeks, the improvement in the mentality and the general health of the patient, and, finally, the discontinuance of bromids, Gordon believes, tend to show that the results from this new method of treatment are very promising.

Encouraged by the first two cases he applied the same treatment to two other cases. The last one, in a little girl, presented certain features that left no doubt of the efficacy of the method. In her case no lumbar puncture was performed so that withdrawal of fluid could not be considered as the cause of her remarkable improvement. Gordon is positive that the improvement in all probability was due to the subcutaneous injections of the cerebrospinal fluid. The four patients treated with subcutaneous injections of cerebrospinal fluid, taken for each from another epileptic, were benefited considerably. The direct effect of this procedure in Gordon's opinion was, and is unmistakable, for the reason that prior to this treatment for months and years the patients received uninterruptedly large doses of bromids and other drugs, and there was, comparatively speaking, very little or no relief. The improvement after the administration of the cerebrospinal fluid was strikingly noticeable not only with reference to the severity of the individual attacks, but also to their frequency. The intervals between the seizures were remarkably long considering their occurrence before the new treatment was instituted. Moreover, in some of the cases the nature of the attacks changed: petit mal took the place of grand mal. The mental hebetude following the epileptic seizures became here exceedingly slight. The treatment, in short, proved to be highly beneficial. No final claim is made as to the curability of epilepsy by this method.

6 Case of Woody Phlegmon of Neck (Phlegmon Ligneux). G. Parker.

1. **Radium and Cancer.**—Drawing conclusions from his own experience, Gould believes he is warranted in saying that in radium we have an agent that in many cases can be used in the treatment of cancer with great hope of success, and that the selective action on cancer cells marks it out from all other known remedies for this disease; but this same experience also shows that it would be a gross exaggeration to speak glibly of radium as the "cure for cancer" in the sense that it will deal with any and every case of this disease. Such is not the case, as it is used at present; but Gould states, remembering that on the one hand the nature of cancer is unknown and most variable in its manifestations, and on the other hand that radium is almost the youngest of the known chemical elements, and has been studied but for a few years, and by relatively few investigators—there is good ground for hope that in the time, which will surely come, when the secret of the nature of cancer is discovered and more is known of the properties of radium, and how to use them better and to control them, we shall have a great extension of the therapeutic value of radium in cancer.

An important feature of the address is the statement of the possible dangers of the radium treatment of cancer. The dangers to which the patients are exposed are sloughing, which may be simply burning of the skin or may manifest itself by necrosis of intestinal wall with formation of fecal fistula; thrombosis in veins close to the site of treatment, hemorrhage, constitutional disturbance, hyperpyrexia, 106 F. after employment of a very large dose; and, lastly, very late, six months or a year after exposure, manifestation of destructive action on normal tissues with the occurrence of fibrotic and hyaline degeneration.

Secondary malignant disease in the liver, pancreas or vertebrae is beyond its reach; so also is primary disease of the stomach, intestine or bladder. In these latter radium can be applied, but its beneficial action may be obtained only at the expense of formation of fistula. If extensive metastasis has occurred, radium is of no use; but if, for example, in epithelioma of the mouth glandular involvement has occurred, the local disease can be treated with radium, the glands dissected out as cleanly as possible, and the operation area irradiated before closing the wound. Again, in inoperable cancer of the intestine radium may be applied so as to reduce the size of the malignant mass, and some palliative operation—short-circuiting, or occlusion—may be performed. Gould thinks that there is a wide field for radium in sarcoma of the long bones, especially the femur, where surgery can suggest only a serious mutilating operation. But where surgery has gained marked success, as in early cancer of the breast, the treatment should still be surgical, though radium workers ask that they should get cases in the early stages, as radium is most likely then to be of benefit.

2. **Triple Syndrome in Abdominal Emergencies.**—Morison emphasizes the fact that the fate of a patient, the victim of an abdominal emergency, depends almost entirely on the skill and promptitude of his doctor, and that any special surgical skill has very little to do with his recovery. It is rare for these emergency operations to require other than ordinary surgical care and skill. Diagnostic skill is the most important factor in recovery.

In all abdominal emergencies there should be three phases or stages, which are as follows: (1) The stage of shock. (2) The stage of reaction. (3) The stage peculiar to each lesion; for example, peritonitis for perforation, acute anemia for hemorrhage, an enlarged gall-bladder or jaundice, for gall-stone, etc. In all of the dangerous lesions pain is severe enough in the first stage to produce symptoms of shock, varying from a feeling that something serious has happened, accompanied by pallor, sweating and feebleness, to such a bad sensation and symptoms as to threaten and, rarely, to cause death. This is the period to which Morison draws special attention because it is of the greatest importance. If looked at fair and square it is difficult to miss the meaning of the symptoms, but there may be only a single chance, the first look, the first visit. Half an hour, even a few minutes later, and, chiefly independent of the sort of lesion, the second phase—that of reaction—has set in, and in a short time the patient may be apparently so well that it is now almost impossible to believe that any dangerous condition is present. This is the time when mistakes are made. The early alarm is too readily forgotten both by patient and doctor and deceptive signs of recovery may mislead both for hours or days. In this, the second, phase the most important evidences are tenderness and rigidity of the abdominal muscles on palpation, and shifting dulness on percussion.

Morison believes that the time has come to make a rule that all cases of abdominal injury and of acute abdominal pain should be sent to a hospital without delay for observation and that the public must be taught that the requirements of present-day surgery cannot be met by extemporized arrangements even in the most perfect houses and that the mortality of serious operations, done at home, is at least four times as great as it is in the suitable environment of a hospital. He cites a number of typical examples.

8. **Bactericidal Action of Organic Silver Salts.**—The results obtained by Rogers are detailed as follows: Silver nitrate.—The most striking point is the remarkable difference in the bactericidal power of silver nitrate against the dysentery bacillus when dissolved in water and diluted broth respectively. In the former it killed the organism in five minutes in dilutions up to 1 in 10,000, the weakest solution tested. On the other hand, with the addition of a little organic matter and salts in the added broth, in one experiment it failed in a strength of 1 in 100 and in another in one of 1 in 500, showing great weakening and irregularity in its effects. The frequent failure of silver nitrate injections in dysentery is thus easily understood.

Organic silver compounds.—With the exception of argyrol, all those tested had a considerable bactericidal action against the dysentery bacillus when dissolved in water, being effective in five minutes in dilutions of 1 in 2,500 and upward. In the presence of a little broth, however, their action was always weaker, but in a variable degree. In the last column of the tables is entered whether any precipitate occurred in the tubes to which broth was added, and it was found that as a general rule those substances which produced such a precipitate acted most feebly in the presence of organic matter and salts, while those in which no change was produced acted best.

Albargin, or silver gelatose, gave the best results in the presence of broth, as it killed the dysentery bacillus within five minutes in a dilution of 1 in 500, or about 1 grain to an ounce, while protargol gave a similar result in one experiment, although it was less efficient in a second trial Mercurol, or mercury nucleate, yielded a similar result, but it did not appear to Rogers advisable to inject a mercury compound into the bowel in the subjects of chronic dysentery Argentamin (silver phosphate dissolved in ethylenediamin solution) was only active in a 1 in 250 solution in weak broth and is not so active or so convenient a preparation as the foregoing

The remaining three silver preparations, collargol, ichthargan and argyrol, had little or no action in the presence of broth on the dysentery bacillus Both potassium and calcium permanganate were effective up to a 1 in 2,500 solution in water, but completely failed in the presence of broth, being precipitated and rendered inert by the organic matter present Boracic acid and quinin bisulphate (which has been so much used as a bowel wash in amebic dysentery) have little or no bactericidal action on the dysentery bacillus even in distilled water

16 **Quinin Alkaloid**—MacGilchrist claims that precipitated quinin base is the best all round form in which to administer quinin by mouth, it can be administered intravenously, and it is preferable to any quinin salt in cases in which hemoglobinuria is dreaded

Journal of Obstetrics and Gynecology of British Empire, London

November, XXIV, No 5, pp 249 286

19 Serodiagnosis of Pregnancy R L M Wallis
20 *New Form of Pelvigraph D Dougal
21 Pelvimetry D Dougal
22 *Description of Ductless Glands from Case of Acute Thyroid Enlargement of Pregnancy C White

20 **New Form of Pelvigraph**—The principle of the instrument devised by Dougal is described as follows by him Two rigid metal arms are connected together by a pair of cross bars in such a way as to allow free movemeent in the vertical plane, both arms remaining parallel throughout and moving synchronously with one another A pivot joint is fitted to one of the cross bars, and connects this portion of the instrument to a metal stand provided with a weighted foot piece and having a vertical draughting board attached to it To the extremity of one arm is fixed a pencil, and this, traveling over the draughting board, records the position at any moment of the other arm which is passed into the vagina and placed on any part of the anterior or posterior pelvic walls An exact reproduction of the contour of the pelvic cavity in the median plane can thus be obtained and the various diameters accurately estimated

22 **Acute Thyroid Enlargement.**—White examined the thyroid, thymus, kidneys, suprarenals, ovaries and pituitary gland of a woman who was naturally delivered of a male child weighing 6 pounds 2 ounces without any special difficulty, the child was quite normal The following day severe bronchitis was present with marked dyspnea and inspiratory recession of the intercostal spaces Neck measurement was given as 16 inches The dyspnea and cyanosis increased and death occurred the next day An autopsy made twenty hours later showed acute bronchitis to have been present There was no laryngeal or tracheal stenosis

The thyroid showed regular enlargement and appeared to be solid except for one cyst 3 cm in diameter on its posterior aspect There were no hemorrhages into its substance The thymus formed a long tongue shaped mass, measuring 11 by 2 by 1 cm The ovaries were normal in size and appearance, corpora lutea were present Adrenals The left measured 6 by 4 by 1 cm and weighed 9 3 grams It was enlarged by a central adenoma The right was normal in size and appearance and weighed 5 5 grams The pituitary measured 15 by 8 by 6 mm

Numerous sections were cut from different portions of the glands The alveoli varied greatly in size, in places resembling the so called colloid goiter They were mostly lined by a single layer of small cubical epithelial cells whose nuclei stained deeply The appearance was suggestive of the rapid formation of new colloid alveoli Nowhere was there intra-alveolar cell proliferation such as is seen in exophthalmic goiter. No increased fibrosis was demonstrable The colloid was clear and rarely granular, it stained yellow with van Giesen's stain Round celled infiltration and other signs of acute inflammation were absent The thymus was normal Kidney the glomeruli were normal The cells of the tubules were swollen, no excess of fibrous tissue present Ovary both old and recent corpora lutea were present No increased fibrosis Adrenal sections showed little deviation from the normal Pituitary the anterior lobe contained big eosinophil (pregnancy) cells in large numbers, arranged in groups surrounding a central cavity as a rule and most frequently found in the anterior part of this lobe The basophil cells were few in number Large cells whose protoplasm stained very feebly with any stain were frequently seen (exhausted secreting cells, or post mortem change) The colloid was three or four times more abundant than normal The pons nervosa had been invaded by the large eosinophil cells from the anterior lobe

32 Modern Treatment of Lacrymal Obstruction D L Davies

25 **Glycosuria in Liver Affections**—Hepatic diabetes, Labbe and Bouchage find supervenes, as a rule, in heavy eaters It is preceded often by obesity, sometimes by gout or renal lithiasis It is a milk diabetes without any nitrogenous waste, corresponding to the classical type of the *diabète gras* or *arthritique* It is accompanied by the usual manifestations of alteration of the liver hypertrophy of the organ, subicteric complexion, and the presence in the urine of excess of biliary pigments, of brownish red pigment, of urobilin, ammonia, and the amino acids The nitrogen index is low Again, the patients may sometimes have hemorrhages and disturbances due to blood coagulation

The cause of this hepatic diabetes majority may be a general infection that attacks the liver, an intoxication such as by alcohol, which has an affinity for the liver cells More often, according to the authors' observations, it is due to overfeeding, especially on meat The glyco regulator disturbance, as a rule benign, may be cured if the anatomic and functional integrity of the liver can be restored While avoiding excess of carbohydrates, it is important to reduce the quantity of meat ingested, the chief cause of the trouble

27 **Operation for Fixation of Movable Kidney.**—An oblique incision is made by Paterson below and parallel with the last rib, the muscles being carefully divided so as not to injure the last dorsal nerve When the kidney is reached the perinephric fat is removed, so that the organ when in position lies in contact with the muscles The renal capsule is next split from end to end along the convex border, and then stripped for about half its extent from the anterior and posterior surfaces of the kidney The upper three fourths of these two flaps of capsule are now folded back over the part of the capsule which has been left adherent, and are retained in that position by a few stitches passing from the free edge of the flaps to the adherent capsule near the hilus, care being taken not to injure the pelvis These stitches prevent the flaps from slipping back over the denuded renal surface Three fixation stitches of strong catgut are next passed from within outward, about half an inch from the edge, then over the edge and once more through the flap from within outward By this means the part of the capsule in the grip of the stitch is twisted and puckered, and the tendency for the stitch to cut out is diminished These stitches are not tied

1. **Radium and Cancer.**—Drawing conclusions from his own experience, Gould believes he is warranted in saying that in radium we have an agent that in many cases can be used in the treatment of cancer with great hope of success, and that the selective action on cancer cells marks it out from all other known remedies for this disease; but this same experience also shows that it would be a gross exaggeration to speak glibly of radium as the "cure for cancer" in the sense that it will deal with any and every case of this disease. Such is not the case, as it is used at present; but Gould states, remembering that on the one hand the nature of cancer is unknown and most variable in its manifestations, and on the other hand that radium is almost the youngest of the known chemical elements, and has been studied but for a few years, and by relatively few investigators—there is good ground for hope that in the time, which will surely come, when the secret of the nature of cancer is discovered and more is known of the properties of radium, and how to use them better and to control them, we shall have a great extension of the therapeutic value of radium in cancer.

An important feature of the address is the statement of the possible dangers of the radium treatment of cancer. The dangers to which the patients are exposed are sloughing, which may be simply burning of the skin or may manifest itself by necrosis of intestinal wall with formation of fecal fistula; thrombosis in veins close to the site of treatment, hemorrhage, constitutional disturbance, hyperpyrexia, 106 F. after employment of a very large dose; and, lastly, very late, six months or a year after exposure, manifestation of destructive action on normal tissues with the occurrence of fibrotic and hyaline degeneration.

Secondary malignant disease in the liver, pancreas or vertebrae is beyond its reach; so also is primary disease of the stomach, intestine or bladder. In these latter radium can be applied, but its beneficial action may be obtained only at the expense of formation of fistula. If extensive metastasis has occurred, radium is of no use; but if, for example, in epithelioma of the mouth glandular involvement has occurred, the local disease can be treated with radium, the glands dissected out as cleanly as possible, and the operation area irradiated before closing the wound. Again, in inoperable cancer of the intestine radium may be applied so as to reduce the size of the malignant mass, and some palliative operation—short-circuiting, or occlusion—may be performed. Gould thinks that there is a wide field for radium in sarcoma of the long bones, especially the femur, where surgery can suggest only a serious mutilating operation. But where surgery has gained marked success, as in early cancer of the breast, the treatment should still be surgical, though radium workers ask that they should get cases in the early stages, as radium is most likely then to be of benefit.

2. **Triple Syndrome in Abdominal Emergencies.**—Morison emphasizes the fact that the fate of a patient, the victim of an abdominal emergency, depends almost entirely on the skill and promptitude of his doctor, and that any special surgical skill has very little to do with his recovery. It is rare for these emergency operations to require other than ordinary surgical care and skill. Diagnostic skill is the most important factor in recovery.

In all abdominal emergencies there should be three phases or stages, which are as follows: (1) The stage of shock. (2) The stage of reaction. (3) The stage peculiar to each lesion; for example, peritonitis for perforation, acute anemia for hemorrhage, an enlarged gall-bladder or jaundice, for gall-stone, etc. In all of the dangerous lesions pain is severe enough in the first stage to produce symptoms of shock, varying from a feeling that something serious has happened, accompanied by pallor, sweating and feebleness, to such a bad sensation and symptoms as to threaten and, rarely, to cause death. This is the period to which Morison draws special attention because it is of the greatest importance. If looked at fair and square it is difficult to miss the meaning of the symptoms, but there may be only a single chance, the first look, the first visit. Half an hour, even a few minutes later, and, chiefly independent of the sort of lesion, the second phase—that of reaction—has set in, and in a short time the patient may be apparently so well that it is now almost impossible to believe that any dangerous condition is present. This is the time when mistakes are made. The early alarm is too readily forgotten both by patient and doctor and deceptive signs of recovery may mislead both for hours or days. In this, the second, phase the most important evidences are tenderness and rigidity of the abdominal muscles on palpation, and shifting dulness on percussion.

Morison believes that the time has come to make a rule that all cases of abdominal injury and of acute abdominal pain should be sent to a hospital without delay for observation and that the public must be taught that the requirements of present-day surgery cannot be met by extemporized arrangements even in the most perfect houses and that the mortality of serious operations, done at home, is at least four times as great as it is in the suitable environment of a hospital. He cites a number of typical examples.

8. **Bactericidal Action of Organic Silver Salts.**—The results obtained by Rogers are detailed as follows: Silver nitrate.—The most striking point is the remarkable difference in the bactericidal power of silver nitrate against the dysentery bacillus when dissolved in water and diluted broth respectively. In the former it killed the organism in five minutes in dilutions up to 1 in 10,000, the weakest solution tested. On the other hand, with the addition of a little organic matter and salts in the added broth, in one experiment it failed in a strength of 1 in 100 and in another in one of 1 in 500, showing great weakening and irregularity in its effects. The frequent failure of silver nitrate injections in dysentery is thus easily understood.

Organic silver compounds.—With the exception of argyrol, all those tested had a considerable bactericidal action against the dysentery bacillus when dissolved in water, being effective in five minutes in dilutions of 1 in 2,500 and upward. In the presence of a little broth, however, their action was always weaker, but in a variable degree. In the last column of the tables is entered whether any precipitate occurred in the tubes to which broth was added, and it was found that as a general rule those substances which produced such a precipitate acted most feebly in the presence of organic matter and salts, while those in which no change was produced acted best.

Albargin, or silver gelatose, gave the best results in the presence of broth, as it killed the dysentery bacillus within five minutes in a dilution of 1 in 500, or about 1 grain to an ounce, while protargol gave a similar result in one experiment, although it was less efficient in a second trial. Mercurol, or mercury nucleate, yielded a similar result, but it did not appear to Rogers advisable to inject a mercury compound into the bowel in the subjects of chronic dysentery. Argentamin (silver phosphate dissolved in ethylenediamin solution) was only active in a 1 in 250 solution in weak broth and is not so active or so convenient a preparation as the foregoing.

The remaining three silver preparations, collargol, ichthargan and argyrol, had little or no action in the presence of broth on the dysentery bacillus. Both potassium and calcium permanganate were effective up to a 1 in 2,500 solution in water, but completely failed in the presence of broth, being precipitated and rendered inert by the organic matter present. Boracic acid and quinin-bisulphate (which has been so much used as a bowel wash in amebic dysentery) have little or no bactericidal action on the dysentery bacillus even in distilled water.

16. **Quinin Alkaloid.**—MacGilchrist claims that precipitated quinin base is the best all-round form in which to administer quinin by mouth; it can be administered intravenously, and it is preferable to any quinin salt in cases in which hemoglobinuria is dreaded.

Journal of Obstetrics and Gynecology of British Empire, London

November, XXIV, No. 5, pp. 249-286

19 Serodiagnosis of Pregnancy. R. L. M. Wallis.
20 *New Form of Pelvigraph. D. Dougal.
21 Pelvimetry. D. Dougal.
22 *Description of Ductless Glands from Case of Acute Thyroid Enlargement of Pregnancy. C. White.

20. **New Form of Pelvigraph.**—The principle of the instrument devised by Dougal is described as follows by him: Two rigid metal arms are connected together by a pair of cross-bars in such a way as to allow free movemeent in the vertical plane, both arms remaining parallel throughout and moving synchronously with one another. A pivot-joint is fitted to one of the cross-bars, and connects this portion of the instrument to a metal stand provided with a weighted foot-piece and having a vertical draughting-board attached to it. To the extremity of one arm is fixed a pencil, and this, traveling over the draughting-board, records the position at any moment of the other arm which is passed into the vagina and placed on any part of the anterior or posterior pelvic walls. An exact reproduction of the contour of the pelvic cavity in the median plane can thus be obtained and the various diameters accurately estimated.

22. **Acute Thyroid Enlargement.**—White examined the thyroid, thymus, kidneys, suprarenals, ovaries and pituitary gland of a woman who was naturally delivered of a male child, weighing 6 pounds 2 ounces without any special difficulty; the child was quite normal. The following day severe bronchitis was present with marked dyspnea and inspiratory recession of the intercostal spaces. Neck measurement was given as 16 inches. The dyspnea and cyanosis increased and death occurred the next day. An autopsy made twenty hours later showed acute bronchitis to have been present. There was no laryngeal or tracheal stenosis.

The thyroid showed regular enlargement and appeared to be solid except for one cyst 3 cm. in diameter on its posterior aspect. There were no hemorrhages into its substance. The thymus formed a long tongue-shaped mass, measuring 11 by 2 by 1 cm. The ovaries were normal in size and appearance; corpora lutea were present. Adrenals: The left measured 6 by 4 by 1 cm. and weighed 9.3 grams. It was enlarged by a central adenoma. The right was normal in size and appearance and weighed 5.5 grams. The pituitary measured 15 by 8 by 6 mm.

Numerous sections were cut from different portions of the glands. The alveoli varied greatly in size, in places resembling the so-called colloid goiter. They were mostly lined by a single layer of small cubical epithelial cells whose nuclei stained deeply. The appearance was suggestive of the rapid formation of new colloid alveoli. Nowhere was there intra-alveolar cell-proliferation such as is seen in exophthalmic goiter. No increased fibrosis was demonstrable. The colloid was clear and rarely granular; it stained yellow with van Giesen's stain. Round-celled infiltration and other signs of acute inflammation were absent. The thymus was normal. Kidney: the glomeruli were normal. The cells of the tubules were swollen; no excess of fibrous tissue present. Ovary: both old and recent corpora lutea were present. No increased fibrosis. Adrenal: sections showed little deviation from the normal. Pituitary: the anterior lobe contained big eosinophil (pregnancy) cells in large numbers, arranged in groups surrounding a central cavity as a rule and most frequently found in the anterior part of this lobe. The basophil cells were few in number. Large cells whose protoplasm stained very feebly with any stain were frequently seen (exhausted secreting cells, or post mortem change). The colloid was three or four times more abundant than normal. The pons nervosa had been invaded by the large eosinophil cells from the anterior lobe.

25. **Glycosuria in Liver Affections.**—Hepatic diabetes, Labbe and Bouchage find supervenes, as a rule, in heavy eaters. It is preceded often by obesity, sometimes by gout or renal lithiasis. It is a milk diabetes without any nitrogenous waste, corresponding to the classical type of the *diabète gras* or *arthritique*. It is accompanied by the usual manifestations of alteration of the liver: hypertrophy of the organ, subicteric complexion, and the presence in the urine of excess of biliary pigments, of brownish-red pigment, of urobilin, ammonia, and the amino-acids. The nitrogen index is low. Again, the patients may sometimes have hemorrhages and disturbances due to blood-coagulation.

The cause of this hepatic diabetes majority may be a general infection that attacks the liver, an intoxication such as by alcohol, which has an affinity for the liver cells. More often, according to the authors' observations, it is due to overfeeding, especially on meat. The glyco-regulator disturbance, as a rule benign, may be cured if the anatomic and functional integrity of the liver can be restored. While avoiding excess of carbohydrates, it is important to reduce the quantity of meat ingested, the chief cause of the trouble.

27. **Operation for Fixation of Movable Kidney.**—An oblique incision is made by Paterson below and parallel with the last rib, the muscles being carefully divided so as not to injure the last dorsal nerve. When the kidney is reached the perinephric fat is removed, so that the organ when in position lies in contact with the muscles. The renal capsule is next split from end to end along the convex border, and then stripped for about half its extent from the anterior and posterior surfaces of the kidney. The upper three-fourths of these two flaps of capsule are now folded back over the part of the capsule which has been left adherent, and are retained in that position by a few stitches passing from the free edge of the flaps to the adherent capsule near the hilus, care being taken not to injure the pelvis. These stitches prevent the flaps from slipping back over the denuded renal surface. Three fixation stitches of strong catgut are next passed from within outward, about half an inch from the edge, then over the edge and once more through the flap from within outward. By this means the part of the capsule in the grip of the stitch is twisted and puckered, and the tendency for the stitch to cut out is diminished. These stitches are not tied

in the meantime. The kidney is now pushed back into its normal position, care being taken to place the upper pole behind the liver. If attention should not be paid to this point, especially in cases in which the kidney tissues are very lax, it may push the peritoneum in front of it and take up a horizontal position at the under surface of the liver. One end of each of the three fixation stitches is now passed through the muscles and fascia forming the upper margin of the wound, near its posterior angle, and tied as they are passed. The kidney now lies well under cover of the ribs, with its lower pole on a level with the upper margin of the wound. The cavity under the kidney is packed with gauze and a dressing applied. This packing is left undisturbed for six or seven days, but subsequently it is renewed every two or three days till the wound has closed. The gauze gives temporary support to the kidney and relieves the strain on the fixation stitches.

29. **Tuberculous Rheumatism.**—From an observation of over 6,000 cases of pulmonary tuberculosis, Raw has not met with a single case of tuberculous rheumatism—at least, it was not recognized as such. He states that while it is very common to see cases of tuberculous arthritis attacking one or perhaps more joints, it is most rare to meet with a multiple arthritis of the smaller joints in the hands, fingers, wrists and ankles in the course of tuberculosis.

Now he cites in full one case, a primary infection of the neck glands with the bovine bacillus, probably conveyed through milk and absorbed from the tonsils and pharynx. The secondary arthritic infection was evidently through the blood-stream. The von Pirquet reaction was most violent. There was no affection of the lungs or pleurae. Six weeks after the onset of joint symptoms the skin of the legs and feet became red, swollen and brawny, and numerous bullae appeared which soon ruptured, discharging greenish pus. Some of these appeared on the arms; after healing a dark brown stain was left on the skin, which still remains. On the subsidence of the acute symptoms Raw commenced a course of tuberculin T. R. (human) in very small doses, to commence with 0.0001 mg. The injections were given weekly in increasing strengths to a maximum dose of 0.01 mg., and with most welcome result. The glands have subsided to half their previous size, while the joints have become smaller and more movable, although they are still stiff, but painless. The local reaction of the tuberculin at the site of injection was very marked and persists up to the present time.

Examination of the fluid from the joints revealed an excess of lymphocytes, which is, of course, morphonuclear leukocytosis, which occurs in true rheumatism. Raw has seen three cases of this rare condition. They were all secondary to a primary tuberculous focus in the neck glands, which is, in his opinion, almost always caused by the bovine bacillus, and he can find no record of tuberculous rheumatism occurring in the course of pulmonary tuberculosis which is most frequently the result of infection by the human bacillus. It would seem, therefore, that the bovine bacillus is much more likely to find its way into joints and also into the blood-stream, than the human bacillus, which is generally limited in its action to the lungs, larynx and intestines.

Journal de Médecine de Bordeaux

December 14, LXXXIV, No. 50, pp. 805-820

33 *Banti's Disease. Lacouture, Dupérié and Charbonnel.

33. **Banti's Disease.**—The patient in the case described was a woman of 39 and the spleen had been enlarging for seven or eight years, with progressive anemia but no jaundice, ascites; urobilin in the urine, no hemorrhages from congestion in the portal system, no enlargement of lymph-nodes, and no history of alccholism, syphilis, tuberculosis or malaria. The blood was of the chloro-anemic type with 30 per cent. hemoglobin, and the patient had attacks of diarrhea but without mucus or blood in the stools. Nothing in the blood indicated abnormal hemolysis. The condition thus seemed favorable for splenectomy, and the spleen was removed; it weighed 2.6 kilograms and measured 7 by 26 cm. The patient did not rally well and died the twenty-seventh day from the results of an infectious process possibly set up by emboli from the drained focus. The system was too much debilitated and lacked the normal leukocyte defense to oppose effectual resistance to the infection. There have been fifty-seven cases of splenectomy for Banti's disease reported since 1909, it is stated, and the present case brings to ten the number of patients who succumbed shortly afterward. The mortality is thus 19 per cent., which is the same figure as for the sixty-one cases recorded during the nine preceding years. This high mortality shows that as the technic has improved, the splenectomy has been done in more advanced cases. It would perhaps be better to reserve splenectomy for the first and second stages and not attempt such a serious operation as this when the patients are in the later stages of Banti's disease. Done at the proper time, the removal of the spleen permits prompt and practically complete restoration to health.

36 *Milk and Typhoid. C. Porcher and A. Dreyfuss.

36. **Milk and Typhoid.**—Porcher and Dreyfuss describe an epidemic of typhoid at Havre traced to one dairy the milk from which had been guaranteed by the Pharmaceutical Society of the city. This milk was much sought after because of the guarantee, and a somewhat higher price was paid for it than for ordinary milk. It seems, however, that the only requirements were an examination as to its fat content and a negative tuberculin test to show that the cows were free from tuberculosis. No bacteriologic examination of the milk had been made. They discuss the question of legal responsibility under the laws of France.

41. **How Dyspeptics Should Drink.**—With a weak stomach it is of the greatest importance to do all to favor it in its work of digestion and do nothing to hamper it. Leven thinks that much harm is done by permitting dyspeptics to drink within five hours after a meal. They should drink only water or weak tea, for which he suggests an infusion of mallow, orange or linden-flowers or vervain. A teacupful should be taken half an hour before meals and not more than a third or two-thirds of a cup should be drunk with the meal. Roentgenoscopy has shown that normal stomachs do not evacuate all their contents until four or five hours or even more after a meal. Water drunk when the stomach is empty passes rapidly on into the intestine, sometimes in less than ten minutes, but if there is any food in the stomach the water is liable to be retained, possibly for hours. A few mouthfuls of bread may cause retention for several hours of a glass of water taken with or soon after it. Roentgenoscopy has shown that our old idea that the stomach becomes empty in two or three hours after a meal is a mistake; six hours is not at all an unusual interval for the food to remain in the stomach even with normal conditions. The Roentgen ray frequently shows the stomach still distended with contents when the individual supposes it has long been empty and is hungry again, or the reverse. When fluid is retained in the stomach it helps to distend the organ; it makes it heavier and thus drag on its supports and irritate the solar plexus, besides its depressing influence on digestion by diluting the digestive juices. He has witnessed many times the com-

plete relief of palpitations, pseudo angina pectoris, dyspnea, asthma, obesity and nervous symptoms when patients were thus instructed when, how much and how to drink The total ration of drinking fluids he says should be about 400 or 500 gm, that is, a little over a pint during the day, not counting in this the fluid in soups and the breakfast beverage

December 24, XXXIII No 52, pp 613 624

48 *Auto Anaphylaxis as Explanation of Paroxysmal Hemoglobinuria F Widal, P Abrami and E Brissaud

48 **Paroxysmal Hemoglobinuria a Manifestation of Auto-Anaphylaxis.**—Widal and his coworkers have had opportunity to study in detail three typical cases in which dipping the hands in cold water for from five to twenty five minutes invariably brought on an attack of hemoglobinuria It was always accompanied by cramps, difficulty in breathing, nausea, and often by urticaria, pruritus, ecchymoses and sudden edema —in short, by the typical manifestations of anaphylaxis The clinical picture is actually identical with that of anaphylaxis, particularly noticeable in the rapid drop in the blood pressure, the extreme leukopeny—the white corpuscles being driven inward from the periphery, inversion of the normal leukocyte formula, and by the abnormally rapid coagulation of the blood, evidently from transient lack of antithrombin

Anaphylaxis hitherto has been supposed to be connected exclusively with the entrance into the body of some alien albuminoid substance, generally in the form of some serum But in paroxysmal hemoglobinuria the anaphylaxis occurs with the elements already present, and with nothing extraneous except the cold For this and other reasons, it seems plausible to explain the trouble as due to the fact that of the three substances found in normal serum, the complement, the antigen or sensitizer, and the antihemolysin, the latter is not stable as it is in most persons, but is peculiarly susceptible to cold Cold inhibits its action, dissociates it and the complement and antigen, thus released from its antagonistic action, are free to attack the red corpuscles in the circulating blood and destroy them

As the whole trouble is due to the instability of the hemolytic element in the serum, all would be remedied if the conditions could be rendered more stable We know that animals can be protected against anaphylaxis by treating them regularly with repeated injections of minute amounts of the substances which otherwise induce the anaphylaxis Applying this principle in the cases of paroxysmal hemoglobinuria, minute amounts of the patient's own serum were reinjected, and the course of the cases confirmed the efficacy of this method of autoserotherapy The experiences were absolutely convincing, it is stated, they throw light on numerous other conditions, showing that the physical state of the colloids of the blood is an important factor in disturbance of the balance in the organic fluids, and should be regarded in therapeutics

55 *Experimental Research on Intravenous General Anesthesia with Hedonal N Beresnegowsky
56 Technic for Removal of Accessory Thyroid (Normalmethode fur die Operation der Zungengrundstruma) H Matti

49 **Nerve Blocking.**—Hartel and Keppler report their experiences with nerve blocking at the brachial plexus, which they have applied in 200 cases for operations on the arm The technic proved an entire success in all but 5 per cent of the cases, Kulenkampff's directions were followed to the letter In seventeen cases examined with the Roentgen rays, the adjoining half of the diaphragm showed signs of paralysis after the injection of the anesthetic into the brachial plexus, in another case there was slight impairment of its movements and in two no influence on the diaphragm. The paralysis of the diaphragm seems to be an almost regular occurrence, and although it so far has not been the cause of any serious trouble, yet it warns of the possibility of such and it positively forbids the blocking of the plexus on both sides at once Severe pain in the chest and dyspnea were observed in five cases and others have reported untoward experiences of this kind Some injury of the pleura by the needle seems the most plausible explanation for this It warns of the necessity for minute care in the technic and also that the method should not be applied except when institutional care is available The most serious drawback to the method, however, is the danger of permanent injury of the plexus, and they report a serious case of the kind The patient was a healthy woman of 64 who had fractured the right radius the day before The fracture was reduced under local anesthesia by blocking the brachial plexus and a splint was worn for nine days only. The radial nerve had evidently been seriously injured by the anesthetic and paralysis and pains followed with the reaction of degeneration almost complete The other nerves in the forearm were also involved to a lesser extent Not until the end of six months was a tendency to improvement manifest, the patient then could grasp objects and there was no further pain in the arm

50 **Injections into Kidney Pelvis**—Wossidlo had occasion to remove a kidney shortly after a silver salt had been injected into the pelvis for Roentgen-ray work He found deposits of the silver salt at various points in the kidney proper, and this finding was confirmed by experiments along the same line in dogs Great care must be taken to keep the amount injected below the actual capacity of the pelvis, and no injection of a silver salt should be attempted if there is reason to suspect an erosion, tuberculous process, stone or tumor in the kidney, as these are liable to be accompanied by some solution of continuity in which the use of the silver salt is fraught with danger.

55 **Injury from Intravenous Injections of Hedonal for General Anesthesia**—Beresnegowsky has been studying the effect of hedonal on the isolated heart and on the tissues in general. The blood-pressure rapidly drops and the breathing becomes weak and shallow or is liable to stop altogether, the heart action keeping up a few minutes after arrest of the respiration Four out of forty five patients stopped breathing, but were restored by artificial respiration, it had to be kept up for eighteen minutes in one case A thrombus developed in the vein in nine of the cases The patients slept from six to twenty hours after the operation and voided urine and stool unconsciously Eighteen of the forty five patients displayed great excitement when they finally roused; in some it resembled alcoholic delirium In one case over two hours after the operation pulmonary edema developed, two similar cases of fatal pulmonary edema after three and eight hours have been reported Extreme fatty degeneration of the kidneys was found in sixteen of the twenty two animals examined, and the heart, liver and adrenals also showed serious injury His conclusion is that neither hedonal, isopral or veronal are suitable for intravenous anesthesia, in amounts sufficient to produce the desired effect they injure the tissues irremediably Much work has been done in this line in Russia, but to date the problem has not been solved to find an anesthetic that can be injected intravenously, without harm, for operations on the head and neck.

in the meantime The kidney is now pushed back into its normal position, care being taken to place the upper pole behind the liver. If attention should not be paid to this point, especially in cases in which the kidney tissues are very lax, it may push the peritoneum in front of it and take up a horizontal position at the under surface of the liver One end of each of the three fixation stitches is now passed through the muscles and fascia forming the upper margin of the wound, near its posterior angle, and tied as they are passed The kidney now lies well under cover of the ribs, with its lower pole on a level with the upper margin of the wound The cavity under the kidney is packed with gauze and a dressing applied This packing is left undisturbed for six or seven days, but subsequently it is renewed every two or three days till the wound has closed The gauze gives temporary support to the kidney and relieves the strain on the fixation stitches

29 **Tuberculous Rheumatism**—From an observation of over 6,000 cases of pulmonary tuberculosis, Raw has not met with a single case of tuberculous rheumatism—at least, it was not recognized as such He states that while it is very common to see cases of tuberculous arthritis attacking one or perhaps more joints, it is most rare to meet with a multiple arthritis of the smaller joints in the hands, fingers, wrists and ankles in the course of tuberculosis

Now he cites in full one case, a primary infection of the neck glands with the bovine bacillus, probably conveyed through milk and absorbed from the tonsils and pharynx The secondary arthritic infection was evidently through the blood stream The von Pirquet reaction was most violent There was no affection of the lungs or pleurae Six weeks after the onset of joint symptoms the skin of the legs and feet became red, swollen and brawny, and numerous bullae appeared which soon ruptured, discharging greenish pus Some of these appeared on the arms, after healing a dark brown stain was left on the skin, which still remains On the subsidence of the acute symptoms Raw commenced a course of tuberculin T R (human) in very small doses, to commence with 0 0001 mg The injections were given weekly in increasing strengths to a maximum dose of 0 01 mg, and with most welcome result The glands have subsided to half their previous size, while the joints have become smaller and more movable, although they are still stiff, but painless The local reaction of the tuberculin at the site of injection was very marked and persists up to the present time

Examination of the fluid from the joints revealed an excess of lymphocytes, which is, of course, morphonuclear leukocytosis, which occurs in true rheumatism Raw has seen three cases of this rare condition They were all secondary to a primary tuberculous focus in the neck glands, which is, in his opinion, almost always caused by the bovine bacillus, and he can find no record of tuberculous rheumatism occurring in the course of pulmonary tuberculosis which is most frequently the result of infection by the human bacillus It would seem, therefore, that the bovine bacillus is much more likely to find its way into joints and also into the blood-stream, than the human bacillus, which is generally limited in its action to the lungs, larynx and intestines

33 *Banti s Disease Lacouture, Duperic and Charbonnel

33 **Banti's Disease.**—The patient in the case described was a woman of 39 and the spleen had been enlarging for seven or eight years, with progressive anemia but no jaundice, ascites, urobilin in the urine, no hemorrhages from congestion in the portal system, no enlargement of lymph nodes, and no history of alcoholism, syphilis, tuberculosis or malaria The blood was of the chloro anemic type with 30 per cent hemoglobin, and the patient had attacks of diarrhea but without mucus or blood in the stools Nothing in the blood indicated abnormal hemolysis The condition thus seemed favorable for splenectomy, and the spleen was removed, it weighed 2 6 kilograms and measured 7 by 26 cm The patient did not rally well and died the twenty seventh day from the results of an *infectious process* possibly set up by emboli from the drained focus The system was too much debilitated and lacked the normal leukocyte defense to oppose effectual resistance to the infection There have been fifty seven cases of splenectomy for Banti's disease reported since 1909, it is stated, and the present case brings to ten the number of patients who succumbed shortly afterward The mortality is thus 19 per cent, which is the same figure as for the sixty one cases recorded during the nine preceding years This high mortality shows that as the technic has improved, the splenectomy has been done in more advanced cases It would perhaps be better to reserve splenectomy for the first and second stages and not attempt such a serious operation as this when the patients are in the later stages of Banti's disease Done at the proper time, the removal of the spleen permits prompt and practically complete restoration to health

41 **How Dyspeptics Should Drink**—With a weak stomach it is of the greatest importance to do all to favor it in its work of digestion and do nothing to hamper it Leven thinks that much harm is done by permitting dyspeptics to drink within five hours after a meal They should drink only water or weak tea for which he suggests an infusion of mallow, orange or linden flowers or vervain A teacupful should be taken half an hour before meals and not more than a third or two thirds of a cup should be drunk with the meal Roentgenoscopy has shown that normal stomachs do not evacuate all their contents until four or five hours or even more after a meal Water drunk when the stomach is empty passes rapidly on into the intestine, sometimes in less than ten minutes, but if there is any food in the stomach the water is liable to be retained, possibly for hours A few mouthfuls of bread may cause retention for several hours of a glass of water taken with or soon after it Roentgenoscopy has shown that our old idea that the stomach becomes empty in two or three hours after a meal is a mistake, six hours is not at all an unusual interval for the food to remain in the stomach even with normal conditions The Roentgen ray frequently shows the stomach still distended with contents when the individual supposes it has long been empty and is hungry again, or the reverse When fluid is retained in the stomach it helps to distend the organ, it makes it heavier and thus drag on its supports and irritate the solar plexus, besides its depressing influence on digestion by diluting the digestive juices He has witnessed many times the com-

plete relief of palpitations, pseudo-angina pectoris, dyspnea, asthma, obesity and nervous symptoms when patients were thus instructed when, how much and how to drink. The total ration of drinking fluids he says should be about 400 or 500 gm., that is, a little over a pint during the day, not counting in this the fluid in soups and the breakfast beverage.

48 *Auto-Anaphylaxis as Explanation of Paroxysmal Hemoglobinuria. F. Widal, P. Abrami and E. Brissaud.

48. Paroxysmal Hemoglobinuria a Manifestation of Auto-Anaphylaxis.—Widal and his coworkers have had opportunity to study in detail three typical cases in which dipping the hands in cold water for from five to twenty-five minutes invariably brought on an attack of hemoglobinuria. It was always accompanied by cramps, difficulty in breathing, nausea, and often by urticaria, pruritus, ecchymoses and sudden edema — in short, by the typical manifestations of anaphylaxis. The clinical picture is actually identical with that of anaphylaxis, particularly noticeable in the rapid drop in the blood-pressure, the extreme leukopeny — the white corpuscles being driven inward from the periphery; inversion of the normal leukocyte formula, and by the abnormally rapid coagulation of the blood, evidently from transient lack of antithrombin. Anaphylaxis hitherto has been supposed to be connected exclusively with the entrance into the body of some alien albuminoid substance, generally in the form of some serum. But in paroxysmal hemoglobinuria the anaphylaxis occurs with the elements already present, and with nothing extraneous except the cold. For this and other reasons, it seems plausible to explain the trouble as due to the fact that of the three substances found in normal serum, the complement, the antigen or sensitizer, and the antihemolysin, the latter is not stable as it is in most persons, but is peculiarly susceptible to cold. Cold inhibits its action, dissociates it and the complement and antigen, thus released from its antagonistic action, are free to attack the red corpuscles in the circulating blood and destroy them.

As the whole trouble is due to the instability of the hemolytic element in the serum, all would be remedied if the conditions could be rendered more stable. We know that animals can be protected against anaphylaxis by treating them regularly with repeated injections of minute amounts of the substances which otherwise induce the anaphylaxis. Applying this principle in the cases of paroxysmal hemoglobinuria, minute amounts of the patient's own serum were reinjected, and the course of the cases confirmed the efficacy of this method of autoserotherapy. The experiences were absolutely convincing, it is stated; they throw light on numerous other conditions, showing that the physical state of the colloids of the blood is an important factor in disturbance of the balance in the organic fluids, and should be regarded in therapeutics.

56 Technic for Removal of Accessory Thyroid. (Normalmethode für die Operation der Zungengrundstruma.) H. Matti.

49. Nerve Blocking.—Härtel and Keppler report their experiences with nerve blocking at the brachial plexus, which they have applied in 200 cases for operations on the arm. The technic proved an entire success in all but 5 per cent. of the cases; Kulenkampff's directions were followed to the letter. In seventeen cases examined with the Roentgen rays, the adjoining half of the diaphragm showed signs of paralysis after the injection of the anesthetic into the brachial plexus; in another case there was slight impairment of its movements and in two no influence on the diaphragm. The paralysis of the diaphragm seems to be an almost regular occurrence, and although it so far has not been the cause of any serious trouble, yet it warns of the possibility of such and it positively forbids the blocking of the plexus on both sides at once. Severe pain in the chest and dyspnea were observed in five cases and others have reported untoward experiences of this kind. Some injury of the pleura by the needle seems the most plausible explanation for this. It warns of the necessity for minute care in the technic and also that the method should not be applied except when institutional care is available. The most serious drawback to the method, however, is the danger of permanent injury of the plexus, and they report a serious case of the kind. The patient was a healthy woman of 64 who had fractured the right radius the day before. The fracture was reduced under local anesthesia by blocking the brachial plexus, and a splint was worn for nine days only. The radial nerve had evidently been seriously injured by the anesthetic and paralysis and pains followed with the reaction of degeneration almost complete. The other nerves in the forearm were also involved to a lesser extent. Not until the end of six months was a tendency to improvement manifest; the patient then could grasp objects and there was no further pain in the arm.

50. Injections into Kidney Pelvis.—Wossidlo had occasion to remove a kidney shortly after a silver salt had been injected into the pelvis for Roentgen-ray work. He found deposits of the silver salt at various points in the kidney proper, and this finding was confirmed by experiments along the same line in dogs. Great care must be taken to keep the amount injected below the actual capacity of the pelvis, and no injection of a silver salt should be attempted if there is reason to suspect an erosion, tuberculous process, stone or tumor in the kidney, as these are liable to be accompanied by some solution of continuity in which the use of the silver salt is fraught with danger.

55. Injury from Intravenous Injections of Hedonal for General Anesthesia.—Beresnegowsky has been studying the effect of hedonal on the isolated heart and on the tissues in general. The blood-pressure rapidly drops and the breathing becomes weak and shallow or is liable to stop altogether, the heart action keeping up a few minutes after arrest of the respiration. Four out of forty-five patients stopped breathing, but were restored by artificial respiration; it had to be kept up for eighteen minutes in one case. A thrombus developed in the vein in nine of the cases. The patients slept from six to twenty hours after the operation and voided urine and stool unconsciously. Eighteen of the forty-five patients displayed great excitement when they finally roused; in some it resembled alcoholic delirium. In one case over two hours after the operation pulmonary edema developed; two similar cases of fatal pulmonary edema after three and eight hours have been reported. Extreme fatty degeneration of the kidneys was found in sixteen of the twenty-two animals examined, and the heart, liver and adrenals also showed serious injury. His conclusion is that neither hedonal, isopral or veronal are suitable for intravenous anesthesia; *in amounts* sufficient to produce the desired effect, they injure the tissues irremediably. Much work has been done in this line in Russia, but to date the problem has not been solved to *find* an anesthetic that can be injected intravenously, without harm, for operations on the head and neck.

65 Clinical and Experimental Study of Arthrodesis of Ankle by Cramer's Method; *Relations* with Genu Valgum. A. Nussbaum.
66 *Osteoplastic Operations; Eleven Cases. J. Borelius.

57. **Exclusion of the Pylorus.**—Kolb states that he recently reexamined nineteen patients whose pylorus had been closed by throwing a ligature of fascia tissue around it. None of the patients showed the slightest permeability on the part of the pylorus on roentgenoscopy after intervals up to 418 days. The results are as complete as if the pylorus had been cut across. The fascia lata tissue seems the best adapted for the purpose, especially that from the lower third of the thigh, where it is particularly strong and even.

59. **Angioma in Peritendon Tissue.**—Weil gives a colored plate of the large angioma in the forearm of a young piano teacher which he successfully removed, as also in a second similar case. He has found only four cases of the kind on record. There was no pulsation in any instance, but concrements in the angioma were common. The growth never involved the tendon but spread over a larger extent than is common with angiomas in muscle tissue. The angiomas were removed in all the cases on record except in Richet's case; he cured the boy of 10 by injection of ferric chlorid into the growth.

62. **Separation of the Abdominal Wall from the Fascia.**—Stierlin states that separation of the derma from the fascia is seldom recognized until lymph accumulates in the cavity thus formed, causing the region to bulge; the bulge subsides or changes its place with change of position. Undulation is another sign. In the case he reports, the eighty-first on record, he states, the woman's abdomen had been trampled on by a cow, and the operation followed before the lymph had had time to accumulate in the cavity formed by the complete separation of the abdominal wall from the fascia. The thigh is generally the region involved.

63. **Fracture of Neck of Femur in Children.**—Schwarz concludes from the clinical experience at Tübingen that the neck of the femur only exceptionally becomes fractured in children. The primary signs of trouble are inability to use the limb, pain, swelling, contracture in outward rotation and possibly slight flexion, with shortening of the limb and unduly high trochanter. The fracture generally occurs at the point of attachment of the neck, and in its lack of tendency to heal it behaves like the similar fracture in adults. It differs from the latter, however, by the prompt restoration of ability to use the limb, although only with a limp, the leg still rotated outward and in abduction. In the six cases reported in detail the fracture healed with completely normal findings, both functional and roentgenoscopic, in only one case. In two of the cases the fracture consolidated in time but pronounced coxa vara was left, entailing a limp. In one case the fracture healed with great deformity of the entire upper end of the femur, and in two cases the entire neck of the femur wasted away, with complete separation of the epiphysis in one case. It seems to require as severe a trauma to fracture the neck of the femur in children as in adults. In four of the six cases reported the fracture was not recognized until several weeks or months had elapsed after the accident. In the two other cases the fracture was diagnosed and proper immobilization was applied from the first. The outcome was ideal in one case, but the other terminated in severe deformity from wasting away of the neck of the femur.

64. **Operative Treatment of Flat-Foot.**—Els states that the ultimate outcome was most excellent in nearly all the twenty-three patients with serious flat-foot disturbances treated by achillotenotomy by Nicoladoni's technic, as he describes in detail.

66. **Osteoplastic Operations.**—Borelius insists that no special skill is necessary for osteoplasty, particularly when the patient's own tissue material can be utilized. The operations were done for pseudarthrosis in six of his cases and for gaps in the long bones in the other five. In one case the upper end of the humerus was removed on assumption of sarcoma but the trouble proved to be merely a solitary cyst with an island of bone in the center. If the correct diagnosis had been made beforehand, the epiphysis would have been left and the function of the shoulder would probably have been better. A stretch of the fibula was inserted in place of the excised upper end of the humerus in another case and the functional result is excellent. The patient was a girl of 11. The same operation has given also excellent results in the case of a woman of 25 with giant-cell sarcoma.

74 Technic to Arrest Hemorrhage in the Nasopharynx. (Die Tamponade bei Blutungen des Nasenrachenraums.) A. Meyer.

67. **Tardy Manifestations of Syphilis in Bones and Joints.**—Axhausen describes some cases of both the more common gummatous form and of the diffuse affection extending through a large extent of the bone and frequently mistaken for fibrous *ostitis or sarcoma*. In the case of a woman of 28 with syphilis acquired at 18 the arm was much swollen, the spindle-shaped enlargement involving the upper end of the ulna as well as nearly the whole of the humerus. This spread across the joint helped to differentiate it from sarcoma, and a series of roentgenograms show the remarkable subsidence of the bone process under specific treatment until the normal outline had been regained throughout, except that the elbow has become stiff from connective-tissue ankylosis. Syphilitic processes in joints may develop with a sudden stormy onset; in some cases chronic polyarthritis may be the clinical picture. It is now the rule in his service to apply the Wassermann test in every case of chronic arthritis, and in a number of cases it explained why years of treatment for the supposed tuberculosis had failed to benefit; a course of treatment for syphilis soon resulted in a complete cure. One such patient was a woman of 29 who had worn a plaster cast for four months on account of a supposed tuberculous process in the right knee. The Wassermann reaction and the discovery of slight thickening of the front of both tibias corrected the diagnosis, and all symptoms subsided under treatment of the syphilis. Puncture and plaster casts had been applied to two children on the same erroneous diagnosis of tuberculosis of the knee and no benefit had resulted, but both children were soon cured by treatment for syphilis, instituted as soon as the Wassermann test had been applied and given a positive result. In some, the healing was complete; in others there was evidence of rubbing in the joint, which suggests the possibility of trouble later.

An instructive case is that of a boy of nearly 6 who had been treated for a year with plaster dressings on account of pain and swelling in the left knee; the joint became stiff and the pains and swelling persisted. After two years arthrectomy was done, and as the other knee was now painful and swollen, it was immobilized and iodoform-glycerin injected. This joint too became stiff. A year later both elbows and one ankle became swollen. He came into Axhausen's hands then with both knees stiff, both elbows much thickened and the Wassermann was positive. Under treatment for syphilis all the swellings promptly retrogressed, and the elbows became normally and one knee partially movable. There seems little doubt that all the joint affections in this case had been the work of syphilis. On reexamination two weeks ago pain and stiffness in the cervical vertebrae suggested tuberculous spondylitis except that the child held its head as with torticollis. Treatment for syphilis was at once resumed and within the two weeks all these symptoms had disappeared, and with them the headaches.

Without proper treatment the joints are doomed to stiffen while all trouble vanishes as if by magic under the proper measures. He does not give salvarsan to young children, but regards it as indispensable in treatment of older children and adults. Its value is shown particularly in the last case described; the patient was a man of 30 with syphilis acquired seven years before. The joints swelled, the tibias thickened and the pains were severe; in the course of years they became unbearable. He applied to Axhausen begging to have both legs amputated, as he had been treated by numerous specialists and the condition was constantly growing worse. Salvarsan had just made its appearance at that time, and it transformed the patient so that in six weeks he left the hospital free from all symptoms and has had no return of any during the three years since.

69. **Multiple Abscesses in the Liver.**—Heinemann's patient was a young man who at 16 had had acute osteomyelitis; the liver trouble five years later was probably secondary to this. Slowly increasing fever, suggesting typhoid but gradually assuming a remittent type, with chills and enlargement of the liver were the main symptoms. The pulse was 110 or 120 but the general condition kept good. Puncture evacuated pus from a small cavity and the fever dropped. When it began to climb again, he punctured anew and found another small abscess which he evacuated. In this way he kept repeating the punctures whenever the temperature began to go up, with chills, and he thus evacuated eleven small abscesses, none having over 1 to 3 c.c. of pus. They were all about 5 or 6 cm. below the skin, and frequently he had to puncture up to ten times before he could locate the abscess. After each was evacuated he left a small glass drain in the cavity; sometimes the patient was wearing three of these drains at once.

In the course of four weeks fully a hundred exploratory punctures had been made, but the liver did not seem to suffer in the least from being thus honeycombed with puncture holes. It gradually returned to normal outlines and the patient was restored to apparently complete health with no impairment of his wage-earning capacity during the two years to date.

Heinemann's experience with acute osteomyelitis is that its mortality is about on a par with that of cholera; he has witnessed three fulminating cases. Recurrences may be observed a year or more afterward; Heinlein has reported a case in which the interval was thirty-six years before recurrence at the site of the old focus of osteomyelitis in the tibia.

70. **Neurotic Constitution the Primary Cause of Gastric and Duodenal Ulcer.**—Bergmann's research has demonstrated that disturbances in the innervation involved in secretion, motor and sensory functioning in the stomach constantly accompany both duodenal and gastric ulcer; also that in the majority of cases abnormal functioning in other organs depending on the vegetative nervous system is plainly evident. The conclusion follows that drugs to act on the vegetative nervous system are indicated in treatment of gastric and duodenal ulcer. A neurotic general constitution and neurotic phenomena in stomach and duodenum seem to be responsible for the primary erosion and prevent its healing, so that a vicious circle is set up.

71. **Diabetes Mellitus Simulating Diabetes Insipidus.**—Balint's patient was a man of 41, a diabetic, but the clinical picture was that of diabetes insipidus as the kidney did not seem to be permeable for sugar. The consequent retention of sugar tends to induce obesity. He warns that in every case of supposed diabetes insipidus the sugar content of the blood should be examined as this may reveal that the trouble is really diabetes mellitus.

73. **Serodiagnosis of Mental Diseases.**—Münzer applies the term "decentralization" to the modification in our conception of nervous and mental affections since Abderhalden has worked out his biologic tests. They show that in certain affections, such as dementia praecox, hitherto supposed to be entirely a brain affection, there is some organic substratum in other organs than the brain. These affections hence are "decentralized," and this suggests a possibility that methods of treatment may yet be found which will act on them. If dementia praecox is due to perverted functioning of certain ductless glands, it may be possible to influence it by acting on these glands, perhaps by castration or by administering the antagonistic organ extract. The brain must no longer be considered alone but in connection with the other organs.

76. **Treatment of Comatous State.**—When called to an unconscious patient, especially one of whose previous history you know nothing, Grober reiterates that the first step is to avert immediate danger from the heart or respiration, and after this to seek to discover the cause of the coma which usually requires very careful examination of the entire body. When it is impossible to remove the cause, such as a poison by venesection, the stomach pump, vomiting, stimulating the kidneys and purging, or render it harmless by giving an antidote, then treatment can be only expectant and symptomatic, keeping close supervision over the circulation and respiration and sustaining them as needed. Harm is often done by over-zeal, as many of the measures advocated require more or less cooperation on the part of the body which the strength is not equal to at the time. Wait therefore after applying one well considered and carefully applied measure for it to have its effect before attempting another, keeping calm under the pressure of the family and friends. Artificial respiration and stimulants for the heart are the main reliance, but measures to restore and maintain the body heat are indispensable. If there is actual paralysis from the action of a poison, atropin sometimes restores the lost tone to the muscles.

77. **Diagnosis of Duodenal Ulcer.**—Bier analyzes sixty-six cases of duodenal ulcer in which he operated and a few others in which the diagnosis proved erroneous. All but fourteen of the sixty-six patients were men. In another case a chronic appendicitis caused symptoms simulating in every respect the duodenal ulcer picture, but nothing of the kind was found at the laparotomy; the clinical picture was materially modified by removal of the appendix but some of the symptoms persisted unchanged. The condition as a whole was not improved by the operation. In another case a man of 47 had been treated by a quack twenty-seven years before for gonorrhea. He had been given by the mouth a solution of mercuric chlorid, and had had "stomach trouble" ever since. The symptoms finally became those of duodenal ulcer, but the operation revealed that the disturbances were from the old cicatrix left from the action of the chlorid on the stomach walls; the pylorus seemed to be intact. In these cases the classic train of symptoms characteristic of duodenal ulcer were all pronounced. Stiffening of the right rectus

and a tender point to the right of the median line were but rarely found, but occult blood was found in the stools in sixteen of the last series of forty-three cases. In two cases of duodenal ulcer a median-line hernia had been previously operated on. This blundering assumption that a casual median-line hernia is responsible alone for the disturbances is not uncommon with both duodenal and gastric ulcers.

78. Treatment of Dilatation and Diverticulum of the Esophagus.—Starck tells how a person with a diverticulum in the esophagus can keep himself in good condition year after year, like some of the patients who have been under his care for fifteen years. The aim should be to prevent food from getting into the diverticulum and, if it does, to clear it out. This can sometimes be accomplished by reclining in a certain position, by stooping over or by pressure on the throat from without or other maneuver. This should be studied until some measure is found which will relieve. If nothing of the kind can be discovered, then the diverticulum tube must be used. It may be necessary during the meal as the filling of the diverticulum may compress the esophagus so that its lumen is obstructed; in any event the toilet of the diverticulum should follow the meal. Retention of particles of food in the pocket not only irritates the mucosa but the decaying particles make the breath offensive and the retained food keeps stretching the diverticulum larger. For all these reasons the toilet of the pocket is imperatively necessary, and he gives illustrations of the twisted excentric olive metal tips which worm their way into the pocket entrance nearly every time. Straight sounds are directly contra-indicated. The patients must be very careful with their diet; any haste in eating soon avenges itself. Emotions have a remarkable influence on the ability of such patients to swallow; the presence of a guest at the table, or even eating with the family is liable to render it impossible for them to swallow, so that complete isolation at meals is generally to be advised. Substances which seem particularly prone to be caught in the diverticulum had better be avoided, especially all hard and dry articles of food, grapes, salads, etc. Some patients do best with exclusively fluid food. Smoking generally aggravates the disturbances. Some patients do better with cold and others with hot foods; experience is the best guide to the diet. If the above measures fail to relieve and the diverticulum is growing larger, operative treatment should be considered. The outlook is better when there is a narrow neck to the pocket, but the result has been excellent in all his fifty cases in the last dozen years. In the early stages of the formation of the diverticulum, systematic use of the tube with the excentric metal olive tip will frequently open the neck of the diverticulum and stretch it so that all further trouble from it is at an end at once. By preventing the entrance of food or fluids into the pocket for a three week period, feeding the patient exclusively through a stomach tube or otherwise, the lining of the diverticulum has a chance to recuperate, and it may retract to the complete obliteration of the recess. A course of diverted feeding in this way two or three times a year has sometimes proved useful in his experience. Nearly every patient has his own method of eating to prevent disturbance from the food getting into the diverticulum; one can swallow better when he looks at the ceiling, another when he bends his head to the right or left,, another as he stoops his body forward, or presses on the trachea from the front or side or from behind the sternocleidomastoid muscle. Neukirch had a patient who could swallow best when he reclined, lying on his right side. The various postures should be tried until the one giving the most relief is discovered.

79. Behring's Diphtheria Vaccine.—Kissling has applied Behring's new vaccine to immunize 310 children who had been exposed to diphtheria in different wards of the Hamburg general hospital. The prevailing epidemic was unusually virulent as is evident from the fact that in the course of 1913 6 of the physicians in the institution, 10 of the nurses, 5 of the other attendants and 11 of the servants had contracted diphtheria. Of the 310 children treated with the vaccine, 111 were given a second injection and none in this group has contracted diphtheria, and only 8 among the remaining 199. In these cases the patients were convalescing from scarlet fever and the diphtheria was exceptionally mild, or the vaccine did not have time to act before the diphtheria developed; several days are required for the vaccine to complete the immunization. Adults respond with more of a reaction to the vaccine than children. Preexisting disease of any kind does not seem to be a contra-indication. See The Journal, July 5, 1913, p. 71.

81. Acute Poliomyelitis.—Cassel had three child patients—two in one week—with partial or complete facial paralysis and complete reaction of degeneration in all the muscles innervated by the facialis. There was nothing to explain the paralysis except that the children had had mild fever for a day or so before the onset of the paralysis, and the throat was slightly red. While he was puzzling over these cases, three cases of unmistakable epidemic poliomyelitis developed in his practice, and the retrospective diagnosis of an abortive form of the same in the first group was plain. He has since had two other cases of the same facial paralysis. It seems evident that an epidemic of poliomyelitis is under way, he says, in Berlin, and he urges as strict and careful measures for prophylaxis as for scarlet fever, typhoid and diphtheria.

89 Autoplastic Fascia Flap to Close Defect in Trachea. Münnich.

85. Scalenotomy for Apical Tuberculosis.—Sato's monograph is based on pathologic anatomic and physiologic research and experiments on animals, and fills 155 pages, with twenty-three illustrations. He ascribes the predilection of the apex for tuberculosis to defective mechanism of the upper rib, the costovertebral joint for the first rib being defectively developed or deformed. The ossification of the first costal cartilage in front, which Freund regards as primary and the cause for the development of the apical process, is in reality not primary but is the effect of the already installed tuberculosis. Severing the first costal cartilage renders it impossible for the first rib to be lifted in ordinary respiration, and consequently the operation amounts to the immobilization of the lung below. For this reason this operation answers the purpose with apical processes, but the same result can be obtained more easily and effectually, Sato declares, by severing the scalenus muscle. This muscle lifts the first and second ribs in forced respiration, coughing, loud speaking and active movements involving the region. By severing the scalenus muscles the first ribs are no longer lifted and the lungs beneath, especially the apices, are no longer pulled about but rest in quiet, even during coughing. The danger of hemoptysis is thus materially reduced and conditions favoring healing are promoted. He gives an illustration of the technic for this scalenotomy. An oblique incision at the rear margin of the sternocleidomastoid muscle at about the middle of the side of the neck permits access to the anterior scalenus muscle; with an incipient apical process it is sufficient probably to cut this muscle alone. With more advanced processes it may be necessary to sever all three of the scalenus muscles and possibly cut the costal cartilage in addition. The work issues from the pathology institute at Göttingen and concludes with the minute details in regard to conditions in large numbers of non-tuberculous adults and children, compared with similar findings in corresponding numbers of the tuberculous.

90 *Pathological and Clinical Study of the Thymus. H. Klose.
91 Treatment of Rickets. E. Schloss.
92 Pathology and Treatment of Paroxysmal Hemoglobinuria A. Beiss.

90. **The Thymus.**—Klose states that it seems to be demonstrated that the thymus is an indispensable organ in growing dogs, and its absence cannot be compensated for. Thymectomized dogs grow abnormally fat and stupid, with alterations in the bones which correspond rather closely to those observed in rickets, and disturbances in the development of the jaws and teeth. A few of the dogs showed convulsive conditions resembling tetany. Thymectomy causes a gradual decrease in the leukocyte count while the administration of thymus extract causes an increase. Disease or removal of the thymus has a marked effect on the blood-pressure, with decrease in blood-pressure, rapidity of the pulse and finally, heart collapse. Though closely parallel in their action, the thymus and thyroid cannot compensate for one another. Thymectomy causes a hypertrophy of the chromaffine cells of the adrenals and an excess of adrenalin in the blood. There is an antagonism between the sexual glands and the thymus. The development of the reproductive glands at puberty probably causes the involution of the thymus.

Of fifty-six patients operated on for tracheal stenosis from enlarged thymus, forty-three were completely cured by excision of all or part of the thymus. Many cases of infants dying at birth are due to hemorrhage into the thymus. This is much more frequent than is generally suspected. Defectively nourished children frequently show sclerotic atrophy of the thymus. This often coexists with congenital defects of various kinds and is frequently due to inherited syphilis, so that specific treatment should be given a trial in dubious cases. Cysts in the thymus sometimes cause sudden death from hemorrhage. Primary defective development of the thymus in childhood has not received much attention hitherto, but Klose calls attention to the frequent coexistence of this with abnormal mental states. He suggests the importance of further research on the thymus to show whether aplastic and hypoplastic conditions in this gland may not be etiologic factors in cretinism, mongoloid idiocy and chondrodystrophic dwarfism.

98 Colloids of Clay. (Die Kolloide der Tone und Kaoline und die Kaolin-Glycerin-Paste in der Dermatologie.) P. Rohland.

94. **Diet in Kidney Disease.**—Linossier states that all his research points to the fact that if albuminous substances are thoroughly cooked, they exert no deleterious influence on the kidneys. This applies to egg albumin, to meats and to milk as well. The alleged superiority of white over red meat in the diet of nephritics is entirely due, he declares, to the fact that white meat is generally more thoroughly cooked.

95. **Camphor in Pulmonary Tuberculosis.**—Alexander has been advocating since 1889 systematic injection of camphor in pulmonary tuberculosis to sustain the heart which always seems to suffer more or less, either directly or indirectly. He never gives over 0.1 gm. camphor, but repeats this injection every day for a month, then dropping to 0.03 or 0.05 gm. but keeping this up for months without interruption. Even with a tendency to hemoptysis, the camphor answers the purpose without need for morphin as a rule. In the first stage of pulmonary tuberculosis no drugs are needed, but if the fever keeps up and there is a tendency to hemoptysis and emaciation, camphor benefits, he affirms, in every case, no matter how advanced.

99. **Thymus Hyperplasia.**—Haberer remarks that the lymphatic and the thymic status are not identical but may coexist; hyperthymization from hyperplasia of the thymus is often a factor in exophthalmic goiter. It seems to be particularly prevalent in his district (the Tyrol); he lost recently from this cause—the thymic status—six patients in one year, three after operations for cancer of the larynx and one each after an operation on the knee, on the thyroid and on the colon. Since then he has been wary of operating on patients with enlarged or persisting thymus, and refrains from general anesthesia as far as possible. In nine goiter operations he resected part of the thymus in addition to resection of the thyroid, including one case in which thyroidectomy had been done before without a cure. All but one of these patients were women, the age between 13 and 44. Four of the patients had pronounced exophthalmic goiter and two had some symptoms suggesting it. The immediate and late results in every instance were extremely favorable, so that he urges all to examine the thymus in all operations for exophthalmic goiter even when there are no symptoms to suggest hyperthymization; reduction of the thymus may prove more effectual than any operation on the thyroid in some cases.

The patients did better after the operation on the thyroid when the thymus had been resected too; there was none of the threatening symptoms on the part of the heart and respiration to which we are accustomed after thyroidectomy. The thymus should be examined also in all operations for ordinary goiter, especially when there are phenomena on the part of the heart for which there is no entirely satisfactory explanation. It is not uncommon to find changes in the thyroid in such cases resembling the pathologic findings in the goiter in true Basedow. By paying more attention to the thymus in this way we can ward off cases of "thymus death," and by eliminating the thymic factor favorably influence true Basedow. In all his experience, resection of the thymus proved absolutely harmless and a comparatively simple and easy operation. *He does not think it is possible to determine the indications for thymectomy from the predominance of symptoms on the part of the vagus or sympathetic nerve systems; the better plan is to cut out part of the thymus if it is found too large for the patient's age.*

102. **Treatment of Roentgen-Ray Burn.**—Pagenstecher's patient was a man with a tuberculous process in the hip-joint which had been examined several times with the Roentgen rays and had been treated locally by various quacks. After roentgenoscopy again a severe dermatitis developed in the region, but there was no ulceration or necrosis and the dermatitis rapidly healed in six or seven weeks. Five months later the patient scratched the region and an extensive x-ray burn developed which became secondarily infected. After failure of conservative measures Kempf resected the area involved but recurrence again and again in the edges showed that the operation had not been carried far enough. The case teaches the importance of operating from the start without regard to the mutilation, carrying the limits of the excision into absolutely sound tissue, covering the defect later with a skin flap from the vicinity. He illustrates the four-flap technic which he found finally effectual in his case, without injury of vessels, etc. The case demonstrates also the necessity for heeding previous local applications to the region and previous exposures to the Roentgen rays before applying roentgenoscopy again.

103. **Iodin Treatment with Pathologic Thyroid.**—Salis and Vogel report the changes in the blood picture and in the thyroid in fifteen patients with various pathologic conditions in the thyroid and one normal control, before and after treatment with iodin, and in seven others not given iodin treatment.

and a tender point to the right of the median line were but rarely found, but occult blood was found in the stools in sixteen of the last series of forty-three cases. In two cases of duodenal ulcer a median-line hernia had been previously operated on. This blundering assumption that a casual median-line hernia is responsible alone for the disturbances is not uncommon with both duodenal and gastric ulcers.

78. **Treatment of Dilatation and Diverticulum of the Esophagus.**—Starck tells how a person with a diverticulum in the esophagus can keep himself in good condition year after year, like some of the patients who have been under his care for fifteen years. The aim should be to prevent food from getting into the diverticulum and, if it does, to clear it out. This can sometimes be accomplished by reclining in a certain position, by stooping over or by pressure on the throat from without or other maneuver. This should be studied until some measure is found which will relieve. If nothing of the kind can be discovered, then the diverticulum tube must be used. It may be necessary during the meal as the filling of the diverticulum may compress the esophagus so that its lumen is obstructed; in any event the toilet of the diverticulum should follow the meal. Retention of particles of food in the pocket not only irritates the mucosa but the decaying particles make the breath offensive and the retained food keeps stretching the diverticulum larger. For all these reasons the toilet of the pocket is imperatively necessary, and he gives illustrations of the twisted excentric olive metal tips which worm their way into the pocket entrance nearly every time. Straight sounds are directly contra-indicated. The patients must be very careful with their diet; any haste in eating soon avenges itself. Emotions have a remarkable influence on the ability of such patients to swallow; the presence of a guest at the table, or even eating with the family is liable to render it impossible for them to swallow, so that complete isolation at meals is generally to be advised. He illustrates the four-flap technic which he found finally effectual in his case, without injury of vessels, etc. The case demonstrates also the necessity for heeding previous local applications to the region and previous exposures to the Roentgen rays before applying roentgenoscopy again.

103. **Iodin Treatment with Pathologic Thyroid.**—Salis and Vogel report the changes in the blood picture and in the thyroid in fifteen patients with various pathologic conditions in the thyroid and one normal control, before and after treatment with iodin, and in seven others not given iodin treatment.

The findings emphasize the difference in the susceptibility to iodin of a normal thyroid and an exophthalmic goiter. In one case exophthalmic goiter with the typical changes in the blood picture developed under their eyes in consequence of the application of iodin to a wound in the foot.

104. **The Functions of the Spleen.**—Bayer regards the spleen and the thymus as capable of functionally compensating each other; after splenectomy the thymus does the work of the spleen, and after the thymus ceases functioning the spleen takes up its task. He tabulates the *metabolic findings* before and two, and six months and two years after splenectomy in two cases of Banti's disease, and compares them with those from experimental research and other clinical experiences. The data all confirm the multiple functions of the spleen: it retains the iron set free by destruction of blood-cells; it wards off hemolysis, and utilizes the stored up iron in it for production of new cells and hemoglobin, and it produces a hormone which has an inhibiting action on the sympathetic nervous system. The liver can store up iron in the place of the spleen, but it has not such avidity for the iron. With Banti's disease the spleen functioning is seriously impaired as also in myeloid leukemia, but it is not the same function which is impaired in these two affections. In Banti's disease the retention of iron proceeds normally or is even exaggerated, but the spleen has lost the faculty of working it up into new cells. The iron lies in the spleen as unutilized ballast. After removal of the spleen the iron is eliminated in much larger proportions and intestinal functioning is exaggerated from lack of the inhibiting hormone from the spleen—an exaggerated vagotonic condition. His two patients were young women and one has passed through a pregnancy since her splenectomy, normal except for signs of pregnancy nephritis.

105. **Serodiagnosis of Cancer.**—Halpern has been applying all the new methods of serodiagnosis in long series of cancer cases and reports rather disappointing results. He says that most of the methods require such a difficult technic and the outcome is so frequently conflicting that the methods have only a scientific and not a practical interest. The findings are frequently positive even in the non-cancer cases with the Grafe-Römer, the Neubauer-Fischer, and the Brieger-Trebing technics, which materially impairs their reliability. The Kelling and the Freund-Kaminer methods require special suspensions of hen's blood-corpuscles or of carcinoma cells, which render the application of the technics difficult in the clinic. Of the whole list he regards only three of the new methods as actual acquisitions. These are the Ascoli meiostagmin reaction, von Dungern's tumor reaction, and Abderhalden's dialysis method. None of the methods to date has proved so reliable that the diagnosis can be based on it and an operation done or omitted on this ground alone if the clinical findings do not agree with it.

He obtained a positive response with the von Dungern technic in 89 8 per cent. of 79 cases of cancer; with the meiostagmin technic in 84.7 per cent. of 46 cases of cancer, but with the Abderhalden technic, in only 30 of 102 cases of carcinoma and in 5 of 19 cases of sarcoma. This small proportion of positive responses to the Abderhalden technic is remarkable, as mistakes in the technic usually tend to increase the number of positive reactions instead of reducing the number.

114 Sand Better than Brush for Cleaning the Hands. O. Thilo.

106. **Operative Treatment of Tuberculous Effusion in the Pleura.**—Spengler and Sauerbruch apply alternately puncture with measures to induce the retraction of the lung, and they think that this gradual and alternating treatment represents great progress. As the cavity falls in the effusion grows less and less, and the patients become better able to stand more radical operative measures. Four of their thirteen patients treated in this way regained their earning capacity.

107. **Recurring Colic in the Upper Abdomen in Children.**—*Moro has encountered eighteen cases of recurring umbilicus* colic in children between 4 and 14. The recurring attacks of pain suggest chronic appendicitis or duodenal catarrh or helminths, but treatment on these assumptions does not bring relief. The trouble is of nervous origin; most of the children are nervous and excitable, with vasomotor disturbances, and they complain occasionally of pains elsewhere, in the legs. knee or between the shoulder blades. They are generally constipated and the constipation may resist ordinary treatment but yield at once to change of scene. He has been invariably successful in treatment based on the psychic origin of the trouble, first applying a little electricity to the region of the umbilicus, followed by a few strips of plaster over the region and belladonna and gentian pills internally. This often cured the tendency to constipation at one stroke and the colics did not return. The effect of course was exclusively by suggestion. The attacks begin with intense pain *in the region of the umbilicus or radiating upward, and may* last for a few minutes to several hours. They recur with a certain regularity, generally every two or three months, but the temperature was never above normal. Three of the children later became subject to periodic vomiting.

118. **Technic for Duodenal Tube.**—Wolff regards the use of the duodenal tube as great progress in feeding children with stenosis or spasm of the pylorus, the cause of uncontrollable vomiting in infants. In three very severe cases he found no difficulty in getting the children to swallow the tube. The pylorus will often permit the lubricated tube to slip through when it absolutely refuses to allow the passage of even 10 c.c. of fluid stomach content. The great drawback of the method is that one is never sure whether the lower end of the tube is in the duodenum or has rolled up in the stomach. It is inconvenient to apply roentgenoscopy each time; the aspiration test is not always reliable, and when the child vomits a little of the stomach content there is danger that the retching will keep up and interfere with the desired feeding. It is amazing, he adds, parenthetically, to see how the children suffering from inanition begin to pick up at once and thrive when they can be thus properly fed through the duodenal tube. The technic he now advocates is to have the child sip a little aqueous or mucilaginous suspension of some local anesthetic just before it swallows the tube. Then a little fluid food is injected into the tube and the child is made to retch; this brings up some of the food thus taken if the end of the tube is in the stomach; if not, we can be certain the tube is in the duodenum, and the anesthetization of the throat prevents any continuance of the vomiting. As a still further aid in introducing the tube, a preceding injection of atropin may prove useful; he has found that even quite young infants bear without apparent harm 0.00005 gm. of atropin four times a day. This does away with the spasm which generally accompanies the anatomic stenosis. It has been his experience further that the use of the duodenal tube seems to have a favorable action on the stenosis itself, stretching the pylorus and thus removing the cause of the disturbances.

119. **Local Applications of Alcohol for Burns.**—Breitmann states that in an experience of fourteen years he has never witnessed any results with other measures comparable to those which follow immediate application of 60 or 70 per cent. alcohol to burns of the first or second degree. The burned area can be placed in a pan containing the alcohol or treated with compresses kept moistened with the alcohol. The pain is relieved, the inflammation subsides, the blisters retrogress and a dry scab forms, healing proceeding smoothly and leaving no trace of the burn. The shorter the interval after the burn before the alcohol is applied, the better the outcome in every way. When the blisters have not been opened the alcohol does not smart; alcohol is too painful to apply to burns of the third degree. The burned area has been sterilized by the heat, and the alcohol, applied at once, before any germs from without have reached the area, dehydrates, dries and tans the tissues, and under the tanned surface the parts below get a chance to heal aseptically. Alcohol above or below the 60 or 70 per cent. strength does not act so well.

129. **Indications for Operative Treatment of Blood-Vessels.**—Coenen calls attention to what he calls the "collateral sign of adequate circulation," which permits operative treatment of an aneurysm or injured vessel without fear of consecutive gangrene. The portion of the vessel involved is exposed and loosened from its bed and a ligature is applied just above and just below the aneurysm or injury. A clamp is then applied to the artery a little below the lower (peripheral) ligature and the artery is severed between the clamp and the ligature. The blades of the clamp are then opened a little and if bright red blood escapes from the peripheral stump, which the clamp has been compressing, this shows that there is already collateral circulation enough to nourish the tissues below and the aneurysm can be resected with confidence that all will be well. If no red blood oozes from the peripheral stump when the clamp is opened, provision must be made for the blood-supply to the region. He found this sign absolutely reliable in his experience with nine cases of traumatic aneurysm in the Balkan campaign, five of several months' standing.

130. **Treatment of Ascites.**—Kumaris conceived the idea that in ascites the peritoneum loses its absorbing power and a vicious circle is thus set up, tending to perpetuate the ascites. By resecting the parietal peritoneum over a large area, this non-absorbing membrane is done away with, leaving conditions favorable for absorption. He does not know whether this resection of the peritoneum has been done by others, but his experiments on dogs showed that they did not seem to suffer after large patches of the parietal peritoneum had been cut away. The dogs seem to be all in good health to date after intervals up to six months. Encouraged by this, he applied the measure in treatment of old malarial ascites in a woman of 50 who required tapping every fortnight. He resected on each side through an incision 19 cm. long, a square of peritoneum measuring 25x25 cm. The peritoneum was silvery white and much thicker than normal. The edema in the legs retrogressed, the general condition was good and the tendency to ascites seemed to be permanently conquered, but the third week the patient developed fulminating fatal erysipelas.

136. **Treatment of Relapse of Genital Prolapse.**—Weibel writes from Wertheim's clinic that in eight cases the prolapse recurred after the operation utilizing the uterus itself to reenforce the floor of the pelvis, the so-called interpositio uteri vesicovaginalis. He tabulates the details of these eight cases and states that conditions were effectually remedied by shortening the sacro-uterine ligaments and strengthening the perineum, supplemented by fixation of the uterus to the pubis arch and to the levator muscle on each side. The prolapse may recur by the fundus or the cervix presenting at the vulva, but the above technic provides for all contingencies.

144 Auscultation of Transmission through the Thorax of the Tuning-Fork Note. (Trasmissione trans-toracica del suono dei diapason.) C. Minerbi and O. Tenani.

143. **Hookworm Disease in Italy.**—Cavallone states that he has encountered in the last eight years 285 cases of ankylostomiasis in the Vercelli district in northwestern Italy, with a population of 2,225. Those affected do not apply to a physician until they are unable to work longer, and consequently his figures give no idea of the actual prevalence of hookworm. There were twice as many women as men among the patients, and twenty-six children. In some of the cases recurring intense headache was the predominant symptom; in others, amblyopia not benefited by wearing glasses. Two students found it impossible to continue their studies until the discovery and cure of the ankylostomiasis. Uncontrollable hiccough was noted in one case; in others there were frequent syncopes with thready pulse and great general depression. Curvature of the spine or genu valgum retrogressed in two cases after cure of the ankylostomiasis. Epileptiform attacks, delirium and hallucinations in other cases ceased after the cure. The women aborted or gave birth to puny children, the debility of these children in later life contrasting with the robust health of the children born after the ankylostomiasis had been cured. Another point to which he calls attention is the peculiarly rapid fatal course of tuberculosis affecting persons already infested with the hookworm.

151 *Momburg's Belt Constriction for Hemostasis E Ahlstrom

152 Operative Treatment of Gangrenous Hernia in Swedish Hospitals, 664 Cases 1901 1910 J Akerman

151 **Momburg's Method of Hemostasis by Belt Constriction**—Ahlstrom presents all the evidence for and against prevention and treatment of hemorrhage by winding an elastic tube around the trunk below the costal arch His review of the literature and personal experiences fills nearly a hundred pages and is accompanied by five large folding charts giving the minute details of the effect on the blood pressure and respiration, etc, when the constriction was applied to rabbits and dogs He has found records of 127 cases in which the method was applied before or during operations, all but sixteen being in prophylaxis The records of obstetric cases number 246, to which should be added the two he reports from his own practice Contrary to the surgical cases, the method was applied in the obstetric cases for prophylaxis only in four instances (The illustrated description of the technic was published in THE JOURNAL, Oct 30, 1909, p 1519)

The only failures have been from inadequate constriction and this also entails certain disagreeable by effects which should be avoided His conclusions are that the method is reliable, and in obstetric cases the risk of injury from it is insignificant, under the conditions which prevail after delivery The method is particularly valuable for severe hemorrhage from laceration of the soft parts, especially with deliveries in the home, it gives the accoucheur time to attend to the lacerations properly or to have the patient taken to the hospital The method is also extremely useful to arrest severe hemorrhage before or after expulsion of the placenta, it renders tamponing superfluous The hemorrhage from inertia of the uterus does not start up again even after the tube has been unwound When the Credé fails, the constriction not only arrests the hemorrhage but the contractions of the uterus which it starts aid in the separation of the placenta The method is also useful in case of much hemorrhage during curetting for abortion or a mole, when the uterus does not reach up too high to forbid the constriction

The great value and comparative harmlessness of the Momburg technic in maternity cases is counterbalanced by the dangers from it and the liability to failure when the method is applied in current surgical work Its use in this field is very limited, as it is contra indicated when the heart is below par and also with arteriosclerosis, nephritis, exophthalmic goiter, anemia from repeated hemorrhages and debility from septic or tuberculous processes The functional capacity of the heart should always be tested before applying the method in surgical work This is not absolutely necessary in obstetric work as the abrupt rise in the blood pressure which follows the application of the constricting band is counterbalanced by the drop in blood pressure from the obstetric bleeding, especially as the child bearing women as a rule are young and the heart vigorous The surgical application of the method is restricted therefore to operations on the pelvis with which there is reason to fear considerable hemorrhage, but only when the field of operation will permit access to ligate any vessels that may bleed when the constriction is released, thus the indications for the method are mainly with extensive resection of bone in the pelvis, hip or thigh or traumatic injury involving this region The method should not be applied with a vaginal operation Experience has shown that the intestine is not injured by the method, no trace of injury has been found in the obstetric cases The danger is a little more in surgical cases, and persons with bowel affections or with tissues weakened by wasting disease or the like should be excluded from the method The pain of the constriction is generally bearable, but morphin may sometimes be needed

The precautions to be observed are that in obstetric cases the pelvis must be raised when the tube is being wound around the body, this prevents anemia of the brain and slight shock In surgical prophylactic cases the horizontal position is best, to hold back the blood in the legs, but when there has been preceding loss of much blood the pelvis should be raised The most dangerous moment is when the constriction is released; the blood pressure drops suddenly and drops extremely low, unless special pains are taken to prevent this The pelvis should be raised and the legs raised, and a constricting bandage should have been previously applied to the thighs, or possibly the blood should have been expelled from the legs by winding them from the feet upward These bands should be released only very cautiously and slowly and only one at a time, and not until some time has elapsed after the constricting tube has been unwound

The mishaps that have been reported from the method to date can all be explained by the abrupt fluctuations in the blood pressure caused by the application of the constricting belt Ordinary gas stove tubing can be used in an emergency, but this is liable to break, and it is better to have a special elastic tube for the purpose The arrest of the femoral pulse is the sign that the constriction is answering its purpose when used in prophylaxis of hemorrhage A pulse controller is useful to show that the femoral pulse has actually subsided, but if one is not at hand the tube can be wound around once more just as the femoral pulse ceases to be palpable In obstetric cases, the tube should be wound around, stretching the elastic tube, until the hemorrhage stops The arrest of existing hemorrhage is the simplest and most certain means of control

THE AIR AS A VEHICLE OF INFECTION

CHARLES V. CHAPIN, M.D.
Superintendent of Health
PROVIDENCE, R. I.

From time immemorial, and until a very recent period, the air has been considered the chief vehicle of infection. It was certainly so when I became health officer thirty years ago. In Parke's "Hygiene," the standard sanitary text-book of the time, and in the edition of 1883, malaria and yellow fever were considered typical air-borne diseases. Typhoid fever was also said to be largely air-borne as was cholera and dysentery and the diarrheal diseases, and sewer air was alleged an important factor in their production. Typhus fever was thought to be spread by means of a vitiated atmosphere, as was also Oriental plague. My immediate official predecessor, Dr. Snow, a distinguished sanitarian of the time, considered scarlet fever only slightly contagious, but due to some epidemic influence, meaning thereby some general infection of the atmosphere. The late Dr. Janeway of this city taught me that the old water-courses of New York could be traced by the excess of diphtheria in the houses along them, due to the effluvia from the damp and infected soil. The well-nigh universal confidence in the phenolized sheet before the door and the saucer of chlorinated lime in the room as barriers against contagion, illustrate how much the air has been feared.

A great change has taken place within recent years in the attitude of scientific men toward the theory of aerial infection. Many diseases formerly considered air-borne have been shown to be transmitted invariably in other ways, and in others the rôle of infection by air has been shown to be much less important than was formerly believed. Some former theories of the mechanism of transmission by means of the air have been found to be untenable and some of the alleged facts of such transmission have been subjected to much criticism. Perhaps the best manner of setting forth present-day facts and ideas is to follow in a general way the course of their discovery and development.

While there have always been some careful observers, as Richard Mead in the eighteenth century and William Budd in the nineteenth, who doubted the supreme importance of aerial infection, the first effective questioning came from the laboratory. The discoveries of Pasteur and the work of Lister encouraged the current views, as it seemed that such minute forms as bacteria could readily float in the air and the difficulty of explaining how they get into the air from infected materials did not at first seem to be appreciated, for it was assumed, with little thought, that they were freely given off from feces, urine and other discharges and particularly that they were contained in the expired breath. The investigations of Nägeli, Buchner and others, in the late seventies of the last century, demonstrating that bacteria are not given off from moist surfaces and liquids in a state of rest, were disturbing to the old theories.

Lister had recognized the power of the respiratory passages to ensnare the bacteria of the air, though Tyndall was the first to demonstrate the fact that the expired air is sterile, a demonstration which was substantiated by many other observers. But so firmly intrenched were the ideas as to the air carriage of disease that other explanations were sought. This seemed to be especially necessary, as at about this time Koch published his discovery that tuberculosis is a contagious disease due to a bacillus. The fact that in most cases the seat of the lesion is in the lungs seemed to require an air-borne and respiratory origin.

The resistance of bacteria to drying and their transmission on small particles of floating dust were eagerly seized on as an explanation, and the authority of Koch, who urged this as a usual mode of infection in tuberculosis, did much to encourage a decided fear of dust as a vehicle of infection. The investigations by Cornet, in 1885, on the presence of tubercle bacilli in dust greatly increased the fear of dust infection, though Cornet's experiments are really a demonstration that even so resistant and common a bacillus is far from ubiquitous.

A vast amount of work has been done to determine the resistance of different kinds of bacteria to drying and their vitality in dust. The factors affecting the life of pathogenic micro-organisms outside of the body are so numerous that it is not surprising that quite discordant results have been obtained by different observers. Certain it is that some bacteria, as those of cerebrospinal meningitis, gonorrhea and influenza, die so quickly that their carriage on dust is practically impossible. On the other hand, the resistance of tubercle, typhoid and diphtheria bacilli is sufficient to admit of their floating on dust particles. On account of the mechanical obstacles in the way of explaining how substances so difficult to reduce to fine dust as feces and sputum could be dust-borne, other modes of infection were sought for, and in 1897, Flügge showed that infecting bacteria could be carried in the fine droplets of saliva which are thrown from the mouth during loud talking or coughing, but which are absent during quiet respiration. It had previously been shown that bacteria-holding droplets could be thrown into sewer air by the agitation of sewage, and this experimental work had perhaps suggested that similar droplets of saliva might be a means of spreading disease from person to person. The followers of both Cornet and Flügge inferred much more from the work of these investigators than was warranted, or than was claimed by the authors themselves. Because Cornet's guinea-pigs could become infected by clouds of tuberculous dust, and Flügge's pigs contracted tuberculosis when held a short distance in front of a coughing consumptive, one is not warranted in assuming that either dust or droplets are, under natural conditions, the chief mode of infection in tuberculosis, and there is still less warrant for such an assumption for other diseases. There is still less reason for assuming that because bacteria are observed to fall on agar plates from the air of a room the air is infectious, and no reason at all for the assumption that because a few diphtheria or tuberculosis germs survive drying for three or four weeks, diphtheria or tuberculosis are dust-borne diseases.

The question of dosage in causing disease is an all-important one, though it has usually been neglected in bacteriologic work on aerial infection. Winslow, however, appears to have fully recognized the importance of quantitative work, and his careful and extensive experiments on sewer air and on dust and the air of schools and dwellings has served to explain much of the contradictory work of others and to bring bacteriologic and clinical observation in accord. Winslow's first quantitative work was on sewer air. In 1907 careful experiments were made by Winslow in this country and by Horrocks at Gibraltar. The latter succeeded in recovering colon and also typhoid bacilli from the soil pipes of the barracks under quite natural conditions, and, though the number was not determined, he was believed by many to have thus demonstrated the dangerous character of sewer air. The number found by Winslow was so small that he deemed it necessary to make further observations. In nearly 200 liter samples of air from the soil-pipes of various buildings in Boston, he found sewage bacteria only four times, and only when there was splashing of sewage at the place and moment of examination. In such air as would be likely to escape from a drainage system, either from the vent-pipe or from an opening into a house, such bacteria were never found. Under ordinary circumstances, pathogenic bacteria, such as the typhoid or dysentery bacillus, must be far less numerous than are colon bacilli. The entire absence of the latter from 193 liters of sewer air, taken elsewhere than in the immediate vicinity of splashing, shows how slight must be the danger from this source, but perhaps this is best shown by a comparison given in Winslow's own words:

> In a surface water of good quality, like that of New York City, the colon bacillus can almost invariably be isolated from 10 c.c. This means a slight degree of intestinal pollution, but experience has shown that the chance of infection from such a water is but slight; and we drink it without serious alarm. If one were to breathe for twenty-four hours the undiluted air of a house-drainage system, at any point not immediately infected by mechanical splashing, it appears that less than fifty intestinal bacteria would be taken in; for the daily consumption of air is about 10,000 liters, and in 200 liters I obtained negative results from air of this sort. In drinking New York water twice as many colon bacilli are ingested every day, for 1,000 cm. is a small amount for daily consumption. So there would be less danger of contracting disease from continually breathing the air of a vent-pipe, or of a soil-pipe, except where liquid is actually splashing, than from drinking New York water.

Later, experiments were made by Winslow and Robinson to determine the extent to which general air infection in an apartment is caused by droplet infection. Out of 140 liters of air taken at various points in the room immediately after from ten to fifty minutes' loud speaking by a person whose mouth was infected with *B. prodigiosus*, the bacillus was found seven times. Of 74 liters examined for *Streptococcus salivarius*, none were found to contain this normal inhabitant of the mouth. The authors consider that an artificial infection of the mouth may give too high an index of air contamination, while the normal germs of the mouth may be thrown off in smaller numbers than are the disease germs from sick persons. The authors conclude that these experiments furnish "no basis for a belief that tuberculosis or any other disease is contracted to appreciable extent through the inspired air" and are "in harmony with the conviction now generally gaining ground that aerial infection of any sort is a minor factor in the spread of zymotic disease."

Still more recently Winslow has made quantitative studies of acid-forming streptococci in New York City schools. He says:

> It is well established that acid-forming streptococci are among the most abundant forms in the human mouth, while they are absent from sources which have not recently been exposed to human or animal pollution. The numbers of these organisms in schoolroom air were found by Professor Baskerville and myself in preliminary experiments a year ago to be quite small. We then found among 30,000 colonies isolated from 750 plates, exposed in schools with window ventilation, only ten mouth streptococci.
>
> In the present study in the examination of a total of 868 cubic feet of air, we found fifty-two mouth streptococci, or six for every 100 cubic feet of air.
>
> A child breathes less than 100 cubic feet of air during an average school period and these mouth streptococci must, of course, be far more abundant than pathogenic forms. At a rate of four or five mouth streptococci per day the chance of ingesting pathogenic bacteria from the air is seen to be a very slender one.

Although Winslow found so few of the bacteria of human saliva in the air of schoolrooms, on another occasion in various schools in this city he found them in dust in enormous numbers, even up to 100,000 in a single gram. This shows that the presence of germs in indoor dust, representing, as it does, long-continued precipitation, is no indication of the number floating in the air, and it indicates the worthlessness of the deductions which have often been made as to the danger of air-borne infection, from the mere demonstration of the presence of disease bacteria in dust.

While bacteriology has given us facts instead of theory as to disease causation and has made a science of sanitation, bacteriology alone cannot solve all our problems. The study of micro-organisms, pathologic findings, animal experiment and epidemiologic observations, must all be utilized and harmonized to solve the problems of disease transmission. It is for us to trace the effect which modern research has had on the old belief that practically all the infectious diseases are air-borne.

TYPHOID FEVER

Largely owing to the great authority of Murchison, it came to be believed, shortly after the middle of the last century, that the chief cause of typhoid fever was the *effluvia* from decomposing animal matter. When the late King Edward VII, then Prince of Wales, contracted a severe attack of this disease at Sandringham in 1871, the chance escape of sewer gas into his apartments was by every one considered a sufficient explanation of the case. Like others, I was at first possessed by the sewer-gas bogey, but failure to connect cases with this alleged cause began to undermine my faith. The discovery of the typhoid bacillus and more careful epidemiologic study soon determined that the greater outbreaks were usually due to infected milk, or other foods, and it came to be seen that the smaller groups and isolated cases could best be explained by contact infection. Finally, the carrier has been shown to be the link between hitherto unconnected cases. No form of air infection (except dust) has been alleged as a cause of typhoid fever for many years, and the reports of outbreaks of dust-borne typhoid fever in the Spanish and Boer wars and in India are based on the flimsiest evidence.

It is a common experience that typhoid fever is freely treated in the general wards of a hospital and that it rarely indeed extends to other patients, although these patients are breathing the air of the ward, perhaps for weeks at a time. It is not so very rare for the nurses of these typhoid cases to contract the disease, though with the development of aseptic nursing such infections are much less frequent than formerly. The only inference is that this disease is not air-borne in hospital wards, but is spread solely by contact.

CHOLERA, DYSENTERY AND DIARRHEA

Cholera, dysentery and diarrhea were, with typhoid fever, considered to be spread largely by means of air polluted by the discharges of patients. The discovery and study of the micro-organisms causing these diseases, and modern epidemiologic and preventive work, have shown the part played by water, food, contact, flies and carriers, and little room is left for the action of air infection. All of these diseases can be treated in general hospitals freely, without danger of extension to other patients. It has occasionally been alleged, especially in England, that summer diarrhea may be dust-borne, but no more than the seasonal distribution, in the drier months, can be adduced as evidence. Laboratory work, when conducted along quantitative lines, as carried on by Winslow, bedside observations and broad epidemiologic studies, are all in accord in denying to the air any part in the extension of this important group of excrement-borne diseases which only a few years ago we believed might be caused by a whiff of sewer air.

ASEPTIC SURGERY

One of the most interesting changes which has taken place in our conception of the part played by the air as a bearer of infection concerns aseptic surgery. When one considers the origin of modern surgery, one is not surprised at the emphasis which was at first placed on air-borne infection. The researches of Schwann, Pasteur, Tyndall and others on spontaneous generation, putrefaction and fermentation largely consisted of experiments showing that when micro-organisms floating in the air are excluded, putrefaction and fermentation do not take place. The admission of almost any air was found to give rise to the growth of bacteria and the occurrence of changes in the liquids under observation. We all know with what wonderful intuition Lister perceived the likeness of sepsis and suppuration to putrefaction and fermentation. His assumption that the former processes are due to the action of bacteria was, after the course of many years, abundantly verified. Lister's brilliant success in preventing sepsis and suppuration in wounds by destroying the infecting bacteria *in situ* or preventing their ingress was truly marvelous and could have been accomplished only by a man of surpassing imagination and inventive genius. Not only has the principle on which he worked been established, but much of the detail worked out by him remains fundamental in surgical practice to-day. Perhaps the greatest change concerns our view as to the infection of wounds from the air. In the beginning the air was considered the chief source of infection. This was perfectly natural and reasonable in the state of knowledge at the time. The work of Pasteur and Tyndall had shown the ubiquity of putrefactive bacteria and their almost universal presence in the air. Nothing was known of the great variety of bacterial species, or of the numerous influences hostile to bacterial life, or of the difference between spores and vegetative forms, or of the great differences in the resisting power of different species. It had been demonstrated that the admission of ordinary air to the test-tube always caused putrefaction; what more natural than to assume that the admission of air to wounds carried with it the germs of suppuration and that its exclusion was a necessity?

The paramount importance attributed to air infection in surgery is well illustrated by an incident of my intern days at Bellevue Hospital. The first strictly aseptic operation in the wards to which I was assigned, was to be undertaken. The room was washed with phenol, the dressings and instruments were sterilized, as were the body of the patient and the hands of the operator; caps and gowns were worn by all. What was considered perhaps the chief antiseptic service was to be performed by the intern, who arose at an early hour of the summer morning to start the phenol spray which was to disinfect the atmosphere, and which was kept going until the end of the operation. During the operation the surgeon dropped his knife on the floor. He picked it up, wiped it on his gown and continued his work. The incident attracted little notice and caused no comment. Such was the relative importance attributed to contact and air infection in those days. To-day, I think Ochsner reflects the best surgical opinion when he says: "Air infection is not impossible, but practically no wound infection is to be considered except from contact." It is true that most surgeons, at least during abdominal operations, guard against infection by mouth spray, but infection by visible droplets, from every practical point of view, resembles infection by direct contact, and is entirely different from the general infection of an apartment by invisible floating droplets.

Although effort is made to have the air of the operating-room, as all else in it, as clean as possible, surgeons do not hesitate to operate, and do operate with success, in the air of the tenement, which is far from dust-free. In fact, the air of even the operating-room does contain pus germs. Many observations have been made, both in Europe and in this country, on the presence of pus-forming bacteria in such situations, and they are practically always found to be present, appearing, often in very considerable numbers, on the agar plates exposed for their collection. Thus Harrington found in Boston operating-rooms a maximum of 131 colonies per square inch per hour. That such a number of bacteria are but rarely, if ever, capable of infecting a wound doubtless seems surprising to many. That they do not is due, doubtless, partly to the fact that, though still capable of growing on culture medium, their virulence is diminished by drying and exposure to light, and partly by their small number. That the chance of infection depends on the dosage is now an established fact, shown both by animal experiment and clinical observation. That a single germ will cause disease is a myth of the early days of bacteriology. Many, many germs are usually necessary, the number doubtless varying greatly with their virulence, with the species, with the nature of the disease process and with the mode of infection. That numerous living pus-forming bacteria floating in the air fail to infect when falling on the fertile soil of freshly cut tissues or exposed peritoneum should make us scrutinize closely the claim often made that pathogenic bacteria, more sparsely distributed still, can run the gauntlet of the respiratory passages and penetrate mucous surfaces, or reach and infect pulmonary alveoli, or pass thence into the blood-stream. It is not the mere presence of germs but their quantity that counts.

MALARIA AND YELLOW FEVER

Fifteen years ago malaria was considered a perfect example of an exclusively air-borne infectious disease and the virus of yellow fever was thought to be spread chiefly in the same way. It needs no reference of mine to call to your minds the brilliant work of Manson, Ross, Celli, Reid, Carroll and Gorgas which removed these from the list of the air-borne diseases, and, neglecting all modes of infection but the mosquito, stamped out the scourges in their strongholds.

TYPHUS FEVER

Most of you have doubtless seen the tablet in Bellevue Hospital on which are inscribed the names of the six interns who died of typhus fever in the outbreak of 1863-4. Of twenty-one members of the staff sixteen contracted the disease; an impressive record of its contagiousness in those days. That this contagiousness was due to the concentration of the virus in the atmosphere of the hospital was the universal belief of fifty years ago. We can to-day scarcely appreciate the heroism of the young men of those days, who, certain in their own minds of the infection of the air, without thought of themselves, breathed it all day long in the wards while ministering to the afflicted. Until within a few short years ago this belief prevailed, for we find typhus fever classed as an air-borne disease by Ker in 1909, in what is perhaps the best text-book we have on the infectious diseases. Nevertheless, careful observers had begun to note that typhus fever was not as readily transmitted in modern hospitals as it was in crowded prisons and ships or in the Bellevue Hospital of old days. Thus six hundred cases were treated in the City Hospital, Liverpool, without a single case of hospital infection. Wilder says that in the American Hospital in Mexico 144 cases were treated without transfer of the disease. Hay in Aberdeen, while noting instances of infection in the hospital during the outbreak of typhus in 1906, says that they were very few, as compared with former times, and confined to those who were brought in contact with the patients before or at entrance into the hospital. Those who handled the patients after they were cleansed escaped.

Now, thanks to the work of Nicolle, Ricketts and Wilder, and Anderson and Goldberger, carried on with such danger and at such a sacrifice, we have been given what is probably the true explanation of the epidemiologic phenomena of this disease. It has been conclusively shown by these experiments that the body louse can, under ordinary conditions, transmit the disease from man to monkey and from monkey to monkey. Three of these men contracted the disease and Ricketts died. Goldberger's attack came on five days after he was bitten by a presumably infected louse. The seasonal, geographic and social distribution of typhus fever all accord well with the theory that it is transmitted by lice, as does also its decrease in recent years in countries of the most refinement, while it still lingers in others. Formerly our hospitals, as well as our prisons and camps, were vermin-infested. No wonder that typhus fever spread in Bellevue Hospital when it could be said, as in 1837, that some of the chronic patients had not had a change of bedding in three months, while between 1881 and 1893, after the advent of the trained nurse, 1,897 cases were received in the hospitals of this city with extension of the disease to only one of the staff. Surely typhus fever must now be removed from the list of air-borne diseases.

SMALL-POX

A wider infection of the atmosphere has been claimed for small-pox than for any other disease. This claim was supported by what seemed very strong evidence and the local government board of England, the weightiest sanitary authority of the times, crystallized the then current views in the dictum that hospitals for this disease should be located at least a mile from inhabited areas. If the aerial infection of small-pox was effective at such a distance, it is no wonder that it was argued from analogy that other diseases were easily and commonly spread through the air of the sick-room or the hospital ward. It is therefore important to question somewhat in detail the evidence in support of this view. This I have done elsewhere,[1] and will now merely summarize what I have there written. Power's report on small-pox around the Fulham Hospital in London was the immediate cause of the stand taken by the local government board. Power attempted to show that whenever the hospital was occupied by acute cases, the disease developed in the neighborhood, showing a progressive decrease as the distance from the hospital increased. A similar increase around other hospitals in London and in a number of English cities, and extension from the isolation ships in the Thames, has been alleged. On the other hand, the disease did not always spread, even from Fulham, and numerous observers in both England and this country have failed to find any evidence of such extension.

Much of the material published by the English advocates of aerial infection does not stand criticism and analysis. Even at Fulham the thickly populated streets nearest the hospital were not much affected. Other sources of infection for the cases alleged to be due to aerial convection were not excluded, and a further study of the forty-one cases nearest the hospital at Fulham showed that twenty were due to direct contact. In Liverpool in 1902-3, according to the government inspections, the hospitals were the cause of much air-borne small-pox, but Hope, the able health officer of the city, completely riddles their evidence. Government inspectors also claimed aerial convection at Gateshead in 1903-4, but the local health officer showed that of the fifty-six cases on which this conclusion was based, fifty-two were clearly traced to contact with other cases. As for the ships in the Thames, small-pox appeared on the shore nearest the ships, and then gradually extended to a distance of 2 or 3 miles. This sort of an extension is just what would be expected in contact outbreaks. If the infection were air-borne, the near and distant communities would have been affected at the same time. It was claimed by Dr. Thresh that the influence of the ships could be noted at a distance of 4 or 5 miles. It was also claimed that several vessels anchored near the hospital ships developed small-pox twelve days later. That ships leaving London during the period of the extensive outbreak in that city should occasionally carry small-pox with them is not remarkable. Finally, it was admitted that surreptitious communication with the ships occasionally occurred.

---

[1] Chapin, Charles V.: Sources and Modes of Infection, Ed. 2, New York, 1912. 260.

At the time of Power's investigation the control of small-pox was very lax. It is stated that many patients with small-pox walked to the London hospitals for admission, ambulance drivers stopped at public houses, children of the neighborhood rode on the steps, and friends with the patient inside the ambulance. Direct communication with the hospital often occurred. It would be most remarkable, if the disease extends from, say, one hundred cases to the distance of a mile with sufficient intensity to infect many persons, that it should not extend one hundred feet from ten cases or even from one case. Why should we not expect aerial infection frequently to operate at short distances from single cases? Yet such transmission does not occur unless with great rarity. How rare it is for any claim to be made that this disease has been carried across the street from house to house, and how unique a rigid demonstration of such an occurrence would be! How often a single case in a crowded lodging-house, ship's steerage or hospital ward fails to infect others! Yet we are asked to believe that one hundred cases can give rise to a whole circle of cases a half mile away. Either the amount of virus must depend on the number of patients or it must under hospital conditions develop in some marvelous way outside of the body.

Collie,[2] who for many years served in five of the London hospitals, has recently reviewed the evidence derived from them, particularly, that from the Homerton Hospital. He came to precisely the same conclusion as I did as to the fallacy of the theory of aerial transmission. He shows that the disease was not distributed around the hospitals as alleged, that much of it was due to contact infection, that the hospitals are in locations where the disease is rife, that it was often prevalent before the hospitals were opened, that unreported mild cases were very numerous, that the administration of the hospitals was lax and that the disease, as a consequence, was spread from them by personal contact. Collie furthermore shows that the incidence of small-pox in institutions adjoining the Homerton Hospital has been small, very different from what is required by the theory of aerial convection, and he gives figures to show a very small incidence of the disease on "other fever patients" treated in adjoining wards of the same hospital, though a large number of these were unprotected by vaccination.

PLAGUE

With the uncertainty as to the true nature of Oriental plague it is not surprising that, among other theories, as to its mode of infection, aerial transmission held a prominent place. The development and demonstration of the theory that plague is primarily a disease of rodents, and that it is spread to man almost exclusively through the agency of fleas, is a fine example of modern scientific method. In this work both the epidemiologist and the laboratory man played important parts. The most complete and convincing evidence was that furnished by the last British plague commission in India. Some of their experiments, demonstrating the agency of fleas in the propagation of bubonic plague, also demonstrated conclusively the entire absence of air-borne infection. Many experiments were made in infected native villages, in houses in which plague had been rife, and from which the human inhabitants had removed. Numerous rodents were exposed in flea-proof wire cages, or protected by sticky fly-paper, but of course freely exposed to the air of the apartments. As long as fleas could not reach the animals they never developed the disease, but numerous control animals exposed in the same places, but not protected from fleas, became infested with these insects and contracted plague. These experiments are entirely in accord with the experience that cases of bubonic plague may be treated in general hospitals without danger, if only the place is kept free from vermin. At the present time probably all epidemiologists are agreed that air infection plays no part in the spread of the disease.

PNEUMONIC PLAGUE

With pneumonic plague, conditions are very different. This form of the disease is usually highly contagious from person to person. The pulmonary secretion is large in amount and crowded with bacilli. Where this type of disease prevails, insanitary habits prevail also, and the opportunities for contact infection are great. Nevertheless the contagiousness of the disease is so great, that in the especially virulent form, which recently occurred in Manchuria, many observers were led to believe that the disease was easily air-borne, presumably by droplets. The primary focus of infection in a large proportion of cases seemed to be in the larger bronchi, though sometimes it was in the tonsils. Strong and Teague sought to demonstrate the presence of droplets by exposing agar plates held vertically before the patients, or in some instances guinea-pigs were so placed. It was found that no plague bacilli were deposited on the plates during quiet, or even labored breathing, though held within a few inches of the face. When held before coughing patients, even at the distance of a meter, they were commonly infected. The wards were crowded with patients and, owing, it was believed, to the droplets, the care of the patients proved very dangerous for the attendants. This danger seemed to be greatly reduced by wearing masks to prevent breathing the germs. The weather was extremely cold and damp, so that the breath was visible and often condensed on the agar plates. Teague and Barker have shown that plague bacilli in droplets sprayed from an atomizer, die in a few minutes in dry warm air, but live much longer in cold damp air, which fact he suggests may account for the occurrence of most outbreaks of pneumonic plague in the winter months. While it would appear that the air in the hospital wards in which these observations were made was dangerously loaded with bacilli-bearing droplets, it may be that it would be quite different if cases of this disease were treated in a ward with sufficient air space and a distance of say 6 feet between the beds. Dr. Strong is, however, strongly of the opinion that, owing to number and virulence of the bacilli and the amount of sputum, droplet infection is, under any conditions, a grave danger in this disease.

MEDITERRANEAN FEVER

The discovery of the etiology of Mediterranean fever is another brilliant example of the effectiveness of modern scientific methods. In the multiplicity of theories resulting from ignorance, of course, aerial transmission had its place. Even two or three years after Horrock's successful work I met a highly educated priest from Malta, who insisted that goat's milk had nothing to do with the disease, but that it came from poor drainage and the resulting effluvia. Among Horrock's numerous experiments were some in which he showed that the disease could be given to monkeys by making them inhale dust which had been artificially infected with large numbers of *Micrococcus melitensis.* Experiments such as this, under unnatural conditions, have little value. But when Horrocks kept monkeys under natural conditions, in separate cages, close by infected animals, they never developed the disease; in other words, there was no air-borne infection. The coccus of this disease has a considerable resistance to drying, much like that of the typhoid bacillus, and theoretically this might therefore be assumed to be a dust-borne disease. The presence of the germs in the urine of numerous goats which move freely about in the streets lends color to this theory. Horrocks showed that it can be dust-borne, but under natural conditions is not.

INFLUENZA

That influenza is air-borne, even over long stretches of country, was a common theory twenty years ago. That the air has no part in its extension from place to place, but that its presence is always due to the importation of cases, was abundantly proved by the observations of Schmid, Parsons and Leichtenstern. That the disease may be spread within a few feet of a coughing and sneezing patient by means of visible droplets is highly probable. That it is transmitted by floating droplets, or by dust, is not likely, as the bacillus has a low resisting power. Reliable clinical observations as to its extension in hospitals and dwellings appear to be lacking.

Judging from the feeble resistance to drying of the coccus of epidemic meningitis that disease seems unlikely to be air-borne and certainly cannot be dust-borne. The fact that meningitis treated in open wards does not spread also contra-indicates it, though the high proportion of carriers to cases somewhat weakens the argument.

Rather scanty experiment indicates that the virus of epidemic poliomyelitis may possibly be dust-borne, and the possibility of its transmission by house-flies, by biting flies and by direct contact with infected secretions has been demonstrated, but which mode of infection actually prevails under natural conditions we do not know. The fact that the disease occurs chiefly in dusty weather is no more reason for assuming it to be dust-borne than is the fact that it prevails in fly-time proof of its transmission by flies. As in meningitis, absence of infection in hospitals indicates that the air is not an important vehicle of infection.

PNEUMONIA

Although much is said, particularly in semipopular literature about the aerial transmission of pneumonia, we really know nothing of the way in which the coccus of this disease reaches the lungs. Nearly half the population at times carry the germs in the mouth. Pneumonia develops only when bodily resistance is weakened. How the coccus in these cases passes from the mouth to the lungs we do not know. That the more virulent strains sometimes pass from person to person seems certain, but neither pathologic experiment nor clinical observation has as yet shown the mode of transference.

SCARLET FEVER, DIPHTHERIA, MEASLES AND WHOOPING-COUGH

If we regard their frequency and the demands which they make on the practicing physician, the health officer and our hospitals, the most important of the contagious diseases, in this climate, are scarlet fever, diphtheria, measles and whooping-cough. Unfortunately, the laboratory has as yet been able to furnish but little evidence as to the mode of their infection. A great deal of evidence, however, has been furnished in recent years by clinical observations, particularly in hospitals. Within the last dozen years the great importance of contact infection has come to be recognized and hospital men have been learning to guard against the spread of disease in their wards by a technic similar to that made use of by surgeons to prevent the infection of wounds. There have been developed medical aseptic methods which so effectually eliminate contact infection that the part played by other modes of transmission can more easily be determined. The impression that air-borne infection is of small moment has been made on hospital superintendents slowly, but so surely that they have dared and have found it convenient to care for different contagious diseases in rooms opening into a common corridor, or rooms only partially partitioned, the so-called cubicles, or even in one open ward. In the latter case the patients are said to be "barriered," which simply means that there is a card or other indication on the bed that the nurse must take special care in passing from patient to patient. There has resulted a considerable mass of carefully collected data as to the aerial transmission of these diseases.

Scarlet fever and diphtheria have very generally been believed to be air-borne, especially scarlet fever. Great fear is always manifested by a neighborhood in which it is proposed to locate a hospital for these diseases, and until quite recently this fear has been shared by health officers. My own ideas as to the aerial transmission of these diseases began to be greatly modified many years ago, when I noticed that they do not spread from tenement to tenement in the same house, unless there is direct contact. In Providence, both scarlet fever and diphtheria spread to other families in about 7 per cent. of the cases, and a careful study of these extensions shows that they take place almost always, either before the disease is recognized, or because of direct contact afterward.

After our hospital was established it was carefully watched, but no especial incidence of these diseases was noticed in the well-populated tenements distant 150 feet. The most careful study of this alleged influence of the hospital was made in Boston, where it was shown that during the period of the observation no cases occurred within one-eighth of a mile, while in the next eighth of a mile circle there were sixty-eight cases. Similar observations have been made in other cities, and in no place is any evidence forthcoming of extension even between different buildings of the hospital.

As regards diphtheria, there is also most convincing evidence that it is not air-borne, even indoors. Although diphtheria carriers are almost constantly barriered in the scarlet fever building in Providence, and not rarely clinical diphtheria as well, there have been only three cases of cross infection among about five hundred cases.

In the isolation wards, in which different diseases are cared for in rooms opening into a common corridor, with 126 cases of diphtheria and 130 carriers, there has been no extension to the 541 other patients. Rundle in Liverpool, had no extension from 42 cases to 699 others in his open ward. Thomson had only 2 cross infections in over 1,200 cases. All of the English hospital superintendents agree that this disease is not air-borne. The extremely small number of cross infections are admitted to be due to failure in aseptic technic. Many hundreds of students have passed through the diphtheria wards in Philadelphia without contracting the disease. Although diphtheria is not air-borne, the bacilli are among the more resistant bacteria, more resistant than tubercle, influenza, pest bacilli, the cocci of meningitis or pneumonia or the cholera spirillum, and we should expect diphtheria to be more readily air-borne than the other diseases mentioned. Teague found the bacilli on a third of all plates exposed in front of speaking patients. The clinical evidence that diphtheria is not an air-borne disease, when purely bacteriologic evidence indicates that it is likely to be such, should make us suspicious of other bacteriologic deductions, deductions which are likely to be misleading if the quantity of the dose is not critically studied.

The evidence also is very convincing that scarlet fever is not air-borne. One reason why we have believed in the air carriage of scarlet fever is that we believed the desquamating epidermis to be infectious. This we now know is not true. For the best evidence we must again turn to the hospitals in which contact infection is reduced to a low limit by aseptic nursing, but in which there is no air separation. At the Pasteur hospital in Paris there has not been a cross infection of scarlet fever among thousands of patients. None occurred in the open wards at Manchester. Thomson had 5 cross infections in 1.290 patients in cubicles and 7 among 660 patients in separate rooms, though the circulation of air in the latter was less than in the cubicles. Rundle had 2 cross infections, and in both there was contact infection. Caiger, Goodall, Gordon, Peters, Crookshank, Biernacki and other English observers, agree that non-septic scarlet fever is not air-borne in hopitals. In Providence we have not been so successful, as we have had 8 cross infections among the 582 non-scarlet fever cases in our isolation wards. Dr. Richardson, the superintendent, believes that these were due to contact infection, owing to failure in nursing technic, or to the carelessness of interns. Schamberg says that none of the nearly two thousand students visiting the scarlet fever wards in Philadelphia have contracted the disease. Ward maids, who do not touch patients, rarely contract scarlet fever, while nurses and physicians coming within the range of visible droplets and coughed-up masses of sputum not infrequently do contract scarlet fever and diphtheria as well. In private families maids, who do not have the care of the children, practically never contract scarlet fever from them, while the parents and nurses do.

The French seem to have been the first to question whether or not measles is chiefly air-borne. The rapid spread of this disease in all institutions for young children in which it happens to be introduced affords one of the difficult problems of institution management. Grancher, believing that the disease is largely spread by contact, attempted to control it in the wards of the children's hospital in Paris, by means of aseptic nursing, without removing the patient from the ward, and he came to the conclusion that the disease is not air-borne, as did also Rohmer at Cologne.

At the Providence City Hospital measles cases are cared for, together with other diseases, in rooms opening onto a common corridor. There is no attempt at air separation and different diseases are attended by the same nurses and physicians. To October 1 of this year there have been admitted 320 cases of measles and 669 persons suffering from other diseases. During most of the time measles was present. During the first nineteen months, 38 cases were admitted with only one cross infection. Then we had three outbreaks, causing in all 23 cases but since May, 1912, there have been but 2 cross infections derived from the 139 cases of measles cared for in this building. The fact that during many months numbers of measles cases have been treated with no cross infection, although there is no air separation, suggests that air infection does not readily occur. Then, too, when cross infections do develop, they are quite as likely to be in distant rooms as in opposite ones. To us it seems, not that the virus of measles is air-borne to a distance, but that it is less easily washed from the hands of nurses and physicians than is that of scarlet fever and diphtheria. We admit a failure of our aseptic methods as hitherto practiced, rather than aerial transmission. There is a difference of opinion among the English hospital superintendents, and while Rundle has successfully cared for measles cases in open wards with susceptible children without cross infection, the others believe that at times the disease is air-borne. Goodall refers to one instance in which a measles case remaining in a twenty-bed ward over night caused nine cases, but he does not say how rigidly contact could be excluded. The evidence as to the aerial transmission of measles is conflicting, so that we are not justified at the present time in coming to a definite conclusion. I am inclined from my own experience to the view that it is not.

A comparatively small number of cases of whooping-cough are admitted to hospitals employing aseptic methods so that few data are at hand as to the mode of transmission. Rundle had no extension from thirteen acute cases treated in his open ward. Caiger thinks that it is not readily air-borne and Biernacki finds that cases can be aseptically nursed provided the beds are 12 feet apart, though to prevent the expulsion of visible droplets during the paroxysms he advises a canopy over the head of the bed. At Providence, twenty-five cases have been treated in the isolation rooms and some cases in other wards without transfer. The only extension in the hospital has been from unrecognized cases among diphtheria patients in which there was direct contact. Richardson is strongly of the opinion that the disease is not air-borne.

CHICKEN-POX AND RUBELLA

There is also difference of opinion as to the aerial transmission of chicken-pox in hospital wards. Most of the English observers think that at times it may be so carried. Goodall and Rundle think otherwise and their opinion is shared by Richardson in Providence.

Caiger does not think that rubella is easily air-borne, for he received 82 cases in his cubicles during eighteen months, and for several months there were from 6 to 8 cases in the wards at a time, yet there were only 2 cross infections. In the isolation wards of the hospital in Providence 37 cases have been admitted with no cross infection among nearly a thousand other patients admitted. At one time 3 cases developed in the diphtheria ward where they had been cared for by a nurse who was coming down with the disease.

TUBERCULOSIS

As tuberculosis has its chief, and apparently primary, seat in the lungs, it was only natural to assume that the route of infection is by the inspired air. Koch's studies on the resistance of the bacillus and its survival in dust greatly encouraged this view, as did the extensive observations of Cornet as to the presence of the germs in dust obtained in the neighborhood of careless consumptives. Then came Flügge, who attempted to show that dust is of little moment, but that infection by floating droplets is the chief mode of infection. The somewhat active controversy between the followers of these two men has, I think, merely served to convince most of us that under the conditions of the experiments both dust and droplets are capable of causing the disease. In tuberculosis, the pathologists take a prominent part in the discussion of causation, but are at variance as to where the primary lesion is to be found and whether the bacillus enters by the respiratory or alimentary tract. Many think that most tuberculous infection dates back to early life, and not a few derive it from the ingestion of milk, though this latter view seems to be losing ground. The weight of evidence derived from these lines of study seems to indicate that the infection is commonly, if not usually, air-borne, and that the primary lesion is in the respiratory tract. There are not a few, however, who hold that contact infection plays a prominent, if not the larger part, in the distribution of the disease and that bacilli-holding sputum carried to the mouth and nose in countless ways reaches the lungs by insufflation or by absorption through the tonsils or through lower sections of the alimentary tract.

Tuberculosis is such a chronic disease that it has thus far been impossible to devise observations on human beings which would throw much light on the route of infection. Recourse must be had to animal experimentation, and most of this has been done under conditions far from natural. Still, a good many experiments have consisted in exposing test animals in cages in apartments occupied by consumptive animals or human beings. A large number of tests made by the Department of Agriculture by exposure to animal sources of infection resulted in a very few cases of tuberculosis. Exposure of test animals in cages in rooms with human beings in Germany, France and this country has almost invariably resulted in the development of the disease in some of the animals, but unfortunately in no instance could contact infection be absolutely excluded, except in an experiment made in a house in Providence occupied by a careless consumptive. Here two sets of guinea-pigs were exposed in cages, one set fed by the patient and the other excluded from any possible form of contact. Most of the animals in both sets developed the disease. The animals in the locked cage covered with wire gauze were, I believe, infected by mouth spray, as the patient often held his face right in front of the box and talked to the animals. There is then a good deal of evidence to show that tuberculosis may be, oftentimes, an air-borne disease. This evidence is certainly far more convincing than for any other disease, except perhaps anthrax. If, as seems probable, the air may serve as a vehicle for the carriage of tubercle bacilli it is probably because, in this disease, more germs are discharged indoors in places where they are likely to get into the air than is the case in other diseases, and because the bacilli have a fairly high resisting power.

ANTHRAX

On theoretical grounds, anthrax ought to be more easily air-borne than any other disease. The spores resist drying for many years, their virulence is high and they are, at times, found in large numbers in materials handled by workmen in such a way as gives rise to much dust. Workers in wool and hair, coming from anthrax-infected regions, have always been subject to this disease. Formerly, when no precaution was taken to prevent the breathing of dust, the disease was very much more prevalent than it is now. During nine months, in 1882, thirty-two cases occurred in the woolen industry in Bradford, England, of which twenty-three were of the pneumonic type and presumably due to the inhalation of dust. Last year there were seventeen cases, and of these only three were of the internal type, so that it appears that with increased freedom from dust the latter type of the disease has shown marked decrease while the external type has not. Careful observers in England and Switzerland have noted the occurrence of anthrax in animals grazing on pastures on which dust from wool-sorting or hair-cleansing rooms was blown.

After this review, a summary scarcely seems necessary, or even a formal conclusion. We have seen that a number of important diseases, formerly considered exclusively air-borne, have been shown never to be such. There is little evidence that, among the diseases which commonly occupy our attention in this part of the world, aerial transmission is a factor of importance. In most it is under ordinary conditions of home and hospital, a negligible factor. For tuberculosis alone is there evidence that air-borne infection is a factor of moment, but the last word has not been said as to the etiology of this disease. We may be sure that the sewer-gas bogey is laid, the notion that dust is a dangerous vehicle of every-day infection is unsupported and that mouth spray is usually effective only at short distances.

HYPERACIDITY OF THE STOMACH

ADOLF SCHMIDT, M.D., GEH. MED.-RAT.
Professor of Internal Medicine, Vereinigte Friedrichs-Universität, Halle-Wittenberg
HALLE, GERMANY

There is hardly a single condition concerning which opinion and treatment have so much changed during recent years as so-called hyperacidity of the stomach. Practically this term is taken to mean those cases of increasing gastric disturbances which appear at various intervals after the taking of ordinary food or special kinds of nourishment. The pain is sometimes accompanied by eructations of gas and small quantities of soured fluid (heart-burn). On examination of the gastric contents obtained with the stomach-tube, there is found either hyperacidity, large quantities of normal stomach-juice, or acid gastric juice. Thus we have either hyperacidity or hypersecretion. The latter may be separated into a digestive and a continuous type.

The continuous type of hypersecretion, when appearing periodically, has been called by some authors gastroxynsis. The most serious cases of continued hypersecretion are known as Reichmann's disease or gastrosuccorrhea.

When further analysis of the cases for various abnormal stomach contents is attempted, many difficulties arise from the fact that the contents do not represent a simple mixture of the test-meal and the gastric secretion. In fact, they first undergo certain uncontrollable changes by their evacuation into the duodenum, which occurs almost immediately after eating. Furthermore, hydrochloric acid may be partly neutralized by the alkaline fluid of the duodenum and the mucus produced by the superficial gastric epithelium. Neither the most exact examination of the stomach contents, performed with repeated aspiration during digestion, nor the valuation of the residue by the Matthiew-Raymond method is able to give us a true idea of the different factors here active.

It is important to know if, in the disease spoken of, the amount of secreted hydrochloric acid is the same as in normal conditions.

In consequence of investigations made on the lower animals by Pawlow and on men by Rubow, Hornborg, Bickel and others, the opinion has been almost generally accepted that pure gastric juice has always the same rather high percentage of hydrochloric acid, even under pathologic conditions. According to this opinion we are led to believe that under normal circumstances the pure glandular product is diluted or partly neutralized by alkaline or gastric mucus, since we do not meet such high degrees even in the empty stomach. According to Forschbach and Schutz, we ought further to believe that the different kinds of hyperacidity or hypersecretion arise either from the secretion of stomach juice being too copious or lasting too long compared with the digestive stimulus represented by the test-meal, or by irregularity of the intervals occurring between the gastric secretion and the emptying into the duodenum. Recently Gregerson, by careful investigations, has proved that at least so far as the human stomach is concerned, Pawlow's opinion must be abandoned, unless we presume that the superficial epithelium produces concentrated alkaline fluid, together with pure gastric juice, a suggestion which is rather paradoxical. Comparing the stomach contents after the usual test breakfast (tea and toast) with those stated after the so-called dry testmeal, Gregerson found, shortly afterward, the same amount of fluid and nearly the same percentage of acidity in both cases. Hence we must conclude that the stomach secretion varies considerably in the amount of hydrochloric acid which it contains.

Under pathologic conditions, these variations occur with greater intensity in view of the fact that the gastric secretion, as well as the motility of the stomach, is dependent on the nervous influences which arise not only from the stomach contents, but also from the brain. It is not remarkable that the gastric contents, as well as the other symptoms of the disease, should vary with the state of the central nervous system. Patients themselves will talk of the whims of their stomachs. One suffers regularly from eating sweets, another from taking too much fat and a third stands the same food either badly or well, according to his mood. Nearly all of them agree that sorrow, excitement or other psychic influences increase their complaints.

One of the most interesting questions connected with this disease is whether or not there is an etiologic relationship between the hyperacidity of the stomach contents and the so-called acid pains, gnawing pressure in the stomach some hours after meals and the heart-burn. The common experience of instant cessation of these symptoms after a dose of sodium bicarbonate or other alkaline salts would seem to confirm it. But it is a well-known fact that hyperacidity and hypersecretion will continue even after the symptoms are completely relieved. Moreover, patients with diminished gastric secretion, achylia or hyperacidity complain sometimes of quite similar pains, so that no experienced observer will venture to take the hyperacidity for granted on the basis of anamnesis without confirming the condition by the use of the stomach-tube. As a matter of fact, the question has been decided in the negative by the results of a simple experiment. It has been found that large quantities of highly concentrated hydrochloric acid introduced into a normal stomach (Schmidt took solutions of 5 per cent.) do not produce such pains. The so-called acid pains, therefore, must be due to some other cause, either a spasm of the stomach sphincters or a hypersensibility of the mucous membrane, or hydrochloric acid, or something hitherto unknown. Cinematographic roentgenoscopy of the stomach during digestion, which has reached its highest perfection in the United States, has shown that very often the beginning of the so-called acid pains takes place at the same time as the spastic contraction of the pylorus.

Of more practical importance, but associated with the theoretical points just discussed, is the question whether the state of hypersecretion or hyperacidity occurs as a disease, *per se,* dependent only on nervous cases, or is always based on certain organic lesions such as gastritis, ptosis of the stomach, ulcers, adhesions, scars, gallstones, etc. A short time ago we did not hesitate to take the majority of the cases as pure stomach neuroses, provided that the presence of a clear sign, as hemorrhage or periodic stenosis of the pylorus, was not against it. To-day our opinion has changed chiefly in consequence of the rediscovery of duodenal ulcer and the description of its clinical signs by American and English authors. I shall neither enter into the difficult question of the exact diagnosis of duodenal ulcer, nor discuss the causes of its high frequency in America compared with the small number of cases occurring in Europe. Yet I shall attach weight to the merit of the Mayo brothers and other surgeons who have shown that an ulcer of the duodenal or pyloric region is often hidden by the symptoms of hyperacidity. We always have reason to suspect the presence of such an ulcer when roentgenoscopy reveals that peristalsis, initially increased, stops in the later periods of digestion; that the well known six hours' residue remains, and that these two periods are separated by a spasmodic contraction of the pylorus, which corresponds to the setting in of hunger-pains. Of course, roentgenoscopy gives more convincing signs, among which may be mentioned the deviation of the pylorus to the right, the worm-eaten cap and the constant filling of the duodenal bulbus, but they are seldom to be found in cases of mere hyperacidity running along without vomiting, loss of blood and other decisive symptoms of ulcer. Here I wish to emphasize the importance of a most careful examination by all methods available in each case of hyperacidity or hypersecretion in which there could possibly exist a hidden ulcer of the stomach or the duodenum, or scars, adhesions, etc., caused by them.

If the results are negative we must go on searching for other causes of hyperacidity. Certain rare cases, like beginning cancer of the pylorus, the occurrence of gall-stones and simple catarrhs of the stomach must first be considered. We can take it as a fact that in many liver diseases, especially those accompanied by pains, the secretion of the gastric acid is increased as the result of a reflex influence. There can also be no doubt that some acute, as well as chronic, inflammations of the stomach result in increased acidity, whether they are connected with atonic ptosis or not. These acid catarrhs may cause some difficulty for diagnosis, since the mucous product of the epithelium, the characteristic sign of catarrhal inflammation, is dissolved by the gastric juice, and therefore does not reappear in the washed-out specimen. The patients are afflicted often with an abnormal irritability of the stomach, so that even a little too much free acid leads to a spasm of one or both sphincters. When the stomach is washed, these patients choke continually and vomit violently. Here we encounter the hyperirritability of the mucous membrane already mentioned, which should be considered as a local manifestation of the general nervousness with which most of these patients are suffering. The irritability of the autonomous nervous system in the so-called vagotonic patients sometimes leads to spastic contraction of the stomach vessels, and this phenomenon is regarded by some authors (Bergmann, Roessle), as the very cause of the ulcer.

This shows that the present state of science does not allow a large space for the purely nervous cases of hyperacidity. It is due to the increasing refinement of our diagnostic knowledge that here, as well as in other branches of medicine, the number of those doubtful cases is more restricted, and the opinion is daily spreading that the nervous moment is only an accompanying symptom of an organic lesion, though the nervous feature may completely overshadow the real disease. Yet we should be premature in entirely denying to-day the clinical unit of hyperacidity. We confess, with resignation, that in practical medicine we often must be satisfied in stating the changed chemism of the stomach.

In treatment, the principal point is not to restrict ourselves to the stomach alone, but at once to aim at calming and strengthening the nervous system, the state of which is of so great importance for the comfort of the patient. Some patients suffering with hyperacidity can get rid of their disease in no other way than by giving up their work for some time, leaving their families and undergoing a real confining treatment in a hospital or sanatorium. I demand this in every severe case, and believe that I owe many good results to this procedure.

Naturally we try first to reduce the increased secretion of the stomach by application of medicines. Atropin is known as a substance which diminishes the secretion of the gastric glands as well as those of the salivary and sweat glands. Therefore the extract of belladonna, which at once levels the tonus of the vagus and removes the accompanying spasm of the sphincters, is a popular part of many stomach powders. Von Tabora recommended regular injections of 0.5 or 1 mg. of atropin before meals, but it is surely not advisable to continue this for a long time, if there is a chance of removing the real cause of the illness in another way. The alkalies which have already been taken for a time by most patients not only neutralize the superfluous acid, but, according to Bickel, also stop their production to a certain degree. On the other hand, they irritate the stomach glands, particularly if carbonic acid is set free by their reaction with the stomach acid, for the carbonic acid is not indifferent to the mucous membrane. Therefore, we prefer to give the magnesium oxid instead of sodium bicarbonate, and we combine it with small quantities of belladonna and a purgative salt, such as sodium sulphate. With the latter I intend to produce a transudation of fluid into the intestine and so to diminish the secretion of the stomach glands. The effect of the Carlsbad water, which often proves beneficial, seems, indeed, to result from the favorable combination of alkaline and purgative salts, but it should always be given in small quantities. Some other acid-binding drugs, as powdered charcoal, kaolin and aluminum silicate, act in another way, by mechanical absorption, each of them being worth trying occasionally. More heroic is the cure of Henriques and Hambart, who for a time withdraw all chlorids from the food. Winternitz and Petri of Halle followed a new principle by introducing magnesium peroxid into the stomach. These authors observed that small quantities of hydrogen peroxid diminished even in a pronounced degree the acidity of the stomach contents, and that this fact is based on an irritation of the surface epithelium, the alkaline product of which neutralizes the present acid. Here we have to deal with the opposing effect of one irritation to another. Lastly, silver nitrate belongs to this group. Its excellent effect on hyperacidity is caused partly by its astringent qualities on the secretory cells, and partly by blunting the hyperirritability of the mucous membrane. For the latter purpose it is to be given as a medicine to be taken half an hour before meals; for the former it is used as a solution to rinse the empty stomach in the morning by means of the tube.

As regards the diet, which is perhaps even more important than the treatment by medicine, opinions differ, though some controversial points are already cleared by the results of experimental medicine. There is no doubt that all kinds of foods and drinks which belong to the class of secretory stimulants must be avoided, as, for example, too much salt, sparkling drinks, high-percentage alcoholics, coffee, meat-juices or extracts of beef, and spices. More difficult is the question of how to arrange the meals. We distinguish three groups of diet specialists corresponding to the single groups of food; those who prefer albuminates, those who prefer carbohydrates and those who prefer fat. The advocates of the first group emphasize the fact that only the albuminates can bind the hydrochloric acid, and therefore have the same effect as the alkalines. They sometimes go so far as to prescribe that when the pains appear the patients should take regularly some food prepared from meat, eggs, etc., lest the stomach should become empty.

Contrary to this, the advocates of the carbohydrate diet assert that they are more correct, since the ingestion of carbohydrates stimulates the production of gastric acid little or not at all, while albuminates first stimulate and then neutralize the acid. They declare their diet as a rational one superior to the symptomatic albuminate diet. They not only avoid stimulating the production of the acid, but also try to produce a reflux of alkaline juice from the duodenum into the stomach, which is most easily done by taking one or two tablespoonfuls of pure olive-oil before meals.

With regard to these three groups, it must be stated, from a practical point of view, that it is most difficult to give one special kind of food for any length of time. Moreover, it is really unnecessary because experience shows that some other dietary prescriptions are more important. I long ago returned to a mixed food and am quite satisfied with it, but strictly observe the following rules, which I believe to be decisive:

1. All food must be well cooked and most carefully minced. This order is based on my own theory that the chief business of the stomach is to reduce the food into small pieces, not by its muscular force, but by chemical influences. These influences consist in the dissolution of the intermediate substances, the connective tissue of meat and fat, the gluten of the bread and the so-called "middle lamina" of the vegetables. As to the connective tissue, I have shown that only the gastric juice is able to digest raw or insufficiently cooked connective tissue, and that during the digestion of meat in the stomach it is always connective tissue which is first dissolved, so that the muscular fibers are set free. This phenomenon is the base of the connective-tissue proof which is a part of my test diet.

As to the disintegration of bread in an efficacious gastric juice and its remaining compact in achylia or hyperacidity, it is sufficient to mention the phenomenon which is generally known as amylorrhexia. The middle lamina of the vegetables is not really dissolved by the stomach juice, but is only prepared by it for dissolution in the alkaline intestinal juice. In this way the chemical stomach work leads to the reduction of all sorts of food into small pieces, and this is a much more significant act of the organ than solution of albuminous matter, as the latter is more surely and with more power effected by pancreatic juice. As the food pieces are broken up by the chemical influence of the gastric juice, they are pushed into the duodenum. Pieces not quite broken up remain for a long time in the stomach, while fluids are rapidly pushed forward. This process is also of importance for the evacuation of the stomach.

2. The stomach must come to rest at least once during the twenty-four hours. This can best be arranged by changing the usual time of meals. The patients should eat large quantities of food in the morning, but only a small quantity in the evening. This means that during the forenoon, when, according to my experience, the patients suffer the least from their pains, they should take two or three meals with intervals of two hours so that there is little appetite left for lunch. After lunch *they do not take anything until 7 p. m., when only* porridge is given. They will now fast until the next morning, and this change also has the advantage that the production of gastric acid, which has been adapted before to lunch and dinner, is regulated in a new manner; the chief secretory reflexes, easily provoked during the former style of living, are now put out of circuit. I can say certainly that I have obtained very good results with this method.

3. Drinking should be generally diminished and restricted to those hours when the stomach is not filled with food. I therefore give the meals rather dry, except the first breakfast and the evening soup, and let the patients drink a short time before lunch or in the afternoon. This prevents loading the stomach, which measure is of special importance to patients suffering from atonic ptosis.

4. If the condition is a severer one or if it is combined with ptosis of the stomach, the patients have to stay in bed for two or three weeks. I think this advice most important. It results from the experience that many patients have their acid pains only when being about or walking, never when lying down. It is further based on the frequency of latent ulcers which lurk behind the symptoms of hyperacidity.

It may be remarked that my dietetic treatment of hyperacidity comes into close touch with the old Leube cure in gastric ulcers. I confess that there is only a certain difference of degree.

I sometimes also order hot compresses in simple hyperacidity, if they give relief to the patient, but I do not apply them continually as Leube does—only twice daily for two hours. For the night I substitute cold hydropathic compresses for them.

Washing the stomach is indicated only if the hyperacidity rises on the basis of a catarrh. Then I rinse the empty stomach in the morning with 1:1,000 solution of salicylic acid or 1:5,000 solution of silver nitrate. Moving the bowels must be carefully regulated.

What is to be done if all these prescriptions do not lead to recovery? This question is equivalent to the other — "Under what circumstances are we allowed to operate in hyperacidity or hypersecretion?" — and cannot be answered generally. Indeed, the nature of the process alone, that is, its being a functional one, cannot always be decisive; it may sometimes be of less importance than the violence of the pains, or the general state of health or the social position of the patient. There is a difference between an apparently neurasthenic patient whose condition remains unchanged after a well-performed gastro-enterostomy which only reduced his stomach pains — for example, an old man who has given up business and can stand his pains if he takes care with his food — and a young man overwhelmed with his business who wishes at all costs to get rid of his sufferings. In the latter case I should advise an operation. There is no doubt, in my opinion, that a case of hyperacidity or hypersecretion, even without complication, which cannot be relieved by internal treatment in order to make the patient fit for work, gives an indication for operation. The manner and procedure of operation cannot be discussed here in detail. This depends on the state of the patient's condition found during operation. If an ulcer of the pylorus or duodenum or a scar is the cause of the hyperacidity, gastro-enterostomy is the right procedure, and if possible, the pylorus should be closed. Perigastritic adhesions must be loosened, and gall-stones removed by cholecystotomy or cholecystectomy. But what is to be done if there is no anatomic lesion at all? In these cases I should advise gastro-enterostomy, but without the closing of the pylorus. The latter can be recommended only if violent pylorospasm is present. The patient should never be allowed to get up and eat anything he wants immediately after recovering from the operation; he must go for some time with the diet and drugs in the same manner as before operation, as the operation does not restore health alone, but only establishes conditions favorable for internal treatment.

Fee-Splitting.—The secret division of fees between two practitioners is indefensible in theory and reprehensible in practice. Viewed from any and every angle, there is no argument that will validate the physician's attitude of auctioneer —selling out his patient to the highest bidder. Nor can the purchaser, by any specious argument, justify his part in so foul a transaction. The practice is rampant not only among those of smaller incomes, but with those enjoying large means as well. Poverty does not justify crime any more than low wages immorality; and certainly, cupidity lays a poor foundation for fair dealing, but builds well for moral strabismus.—Arthur J. Patek, M.D., *Wisconsin Med. Jour.*

SOME POINTS IN THE TREATMENT OF HYPERACIDITY

ESPECIALLY WITH REFERENCE TO THE USE OF HYDROGEN DIOXID *

CHARLES HUGH NEILSON, Ph.D., M.D.
ST. LOUIS

Hyperacidity is usually considered a secretory neurosis of the gastric mucosa. This so-called neurosis is caused by reflex stimulation of the gastric mucosa by disease elsewhere in the body. We may therefore consider hyperacidity as a symptom of disease, rather than a disease itself.

The observant clinician often finds hyperacidity in the overworked, in those who lead sedentary lives with improper food and insufficient exercise, and in those who work under a great strain. He finds it as a common accompaniment of chronic appendicitis. It is frequently encountered in gall-stones, floating kidney, mobile cecum and movable and fallen transverse colon. Women with uterine misplacements, especially women with menstrual disorders, are well-known subjects of this disease. It is one of the early signs of beginning hyperthyroidism and incipient tuberculosis. Ear-troubles and eye-strain are frequently the cause of this condition. It is found in ulcer of the stomach in the majority of cases, and finally many cases are found in which the basic trouble is some nervous or some psychologic disturbance.

Nearly all workers in gastric disease agree that perhaps a majority of dyspepsias and indigestions are cases of hyperacidity.

In these cases of hyperacidity we are generally dealing with a complex affair and not a simple local chemical condition in the stomach. In no pathologic condition is a careful history, a complete detailed and repeated examination so important as in the treatment of this class of cases.

In the treatment of hyperacidity we must therefore first make a correct diagnosis, searching carefully for some cause of this condition. Often the removal of this cause removes the trouble, and the treatment of the chemical condition in the stomach is of minor importance.

In addition to these general or exciting causes, there is a local condition in the stomach itself which must be considered. Any person who has suffered from hyperacidity for any length of time will have certain pathologic changes in the gastric mucosa which must be treated. In a large percentage of these cases there is a concomitant hypersecretion or a continued secretion which must share our attention in the treatment. There is also a troublesome change in the gastric mucosa, called gastric hyperesthesia, which is of great importance to consider in the treatment. Along with these conditions we often find pylorospasm, hypermotility or gastroptosis. These conditions must also be considered in the treatment.

We may divide hyperacidities into the following classes:

1. Chemical hyperacidity with a normal quantity of gastric content after a Boas-Ewald test breakfast.
2. Chemical hyperacidity combined with hypersecretion or with a continued secretion. Here the quantity of gastric content is abnormally and constantly large.
3. Chemical hyperacidity combined with hypersecretion and hyperesthesia.
4. Clinical or symptom hyperacidity with hyperesthesia. In this class of cases we have all the subjective symptoms of a chemical hyperacidity. In these cases we find a normal total acidity, or even a subacidity. The symptoms are due to the hyperesthetic condition of the gastric mucosa which is painful in a normal or even subnormal acid content.
5. In this class we may find any one or a combination of the foregoing together with pylorospasm, hypermotility or peristaltic unrest.

The treatment of hyperacidity may be classified as follows:

1. Removal, if possible, of the general or exciting cause.
2. Treatment of the local condition: (*a*) dietetic; (*b*) medicinal; (*c*) physical therapy.

The local condition is for the most part a chemical affair, and therefore the dietary is a most important feature of this treatment. To diet successfully in any disease, but especially in gastric disease, a knowledge of the physiology and chemistry is important and necessary.

In the gastric juice the most important constituents are the protease enzyme, pepsin and the hydrochloric acid. The hydrochloric acid acts on the proteins, changing them into acid metaprotein, this constituting "combined" hydrochloric acid. This substance loses its distinctive acid properties and produces no chemical irritation to the gastric mucosa. This fact is of vital importance in dieting in hyperacidity cases. It is the free acid which produces the pain and discomfort, and not this combined acid.

Schüle[1] of Freiburg performed on himself the following experiment: On his forearm he cut off two fair-sized pieces of epidermis. On the one denuded surface he placed 0.2 per cent. hydrochloric acid. At once there was an excruciating burning pain. On the other denuded surface he placed 0.2 per cent. hydrochloric acid, which had been saturated with albumin. In this case there was no pain at all.

All dietaries, therefore, for the treatment of hyperacidity ought to include those foods rich in protein, such as eggs, meats in all forms, fish and cocoa, which have a high acid-combining power. These foods will combine with the excess acid and the pain and discomfort will tend to disappear. In many cases beautiful results are obtained; in others the results are not so good.

The explanation of this difference may be as follows:

1. Those patients who have a straight chemical hyperacidity with no hyperesthesia, hypersecretion, etc., do well on a high-protein diet.
2. Those foods which have the highest protein content are stimulating to the gastric mucosa, and more acid may be produced on account of this stimulation. By using a high-protein diet we may increase the quantity of hydrochloric acid instead of lessening it.

In support of this view we have the classification of foods by Bickel,[2] as follows:

1. Foods strongly stimulating to the mucosa: (*a*) raw and cooked meats; (*b*) coagulated albumin; (*c*) yolk of egg; (*d*) skim-milk and casein.
2. Foods which are only slightly stimulating: (*a*) full milk; (*b*) cream; (*c*) pure carbohydrates; (*d*) pure

[2] Bickel: Ein Diätschema für die Behandlung der Sekretionsstörungen des Magens, Verhandl. d. Balneologenkongresses, Berlin, 1910

uncoagulated albumin; (*e*) vegetables—not coarse; (*f*) sweet egg foods.

If we consider the acid-binding power as the essential factor in this diet we must give the foods of Class 1. If we wish a diet that has only a half or two-thirds the acid-combining power, but is far less stimulating to the mucosa, we shall use Class 2.

Any hyperacidity diet which is properly carried out is the same as the so-called ulcer diets. It has this difference, that the hyperacidity diet can more rapidly be changed into the normal or mixed diet. These ulcer diets are well known, the best-known two being the Leube and the Lenhartz diets. The Lenhartz diet is rich in proteins and as such furnishes a high acid-combining power, but it belongs to the class of foods which stimulate gastric secretions.

The Leube diet is in some respects a mixture of Class 1 and Class 2, and to my mind is the ideal diet for general use. I feel that it is especially adapted for more of the hyperacidity cases than the Lenhartz diet.

To diet these patients we must study our case carefully to see with what class of hyperacidity we are dealing. In this connection, however, it is well to remember that in a way each case is a law unto itself and will often need a diet which will not fall under any prescribed diet.

There is another thing of importance in dieting these patients: frequent feedings generally give better results than large feedings at longer intervals. As a rule, large feeding at regular meal-times, with small feedings in between and at bedtime, is ordinarily used.

Before a diet is commenced the physician ought to have clearly in mind a well-mapped scheme for giving the diet. This scheme should not be modified in any way except on order of the physician. It is only by perseverance on the part of both the physician and the patient that good results are obtained. We must remember that patients suffering with hyperacidity must be fed, and well fed. Too often they are underfed.

Recently the sodium chlorid content of the food in these dietaries has received considerable attention by dietitians. Laufer, Hayem, Ewald, Vincent and others have given experimental and clinical evidence that dechlorination is of great importance in reducing acidity.

Recently Richarts[3] strongly advocated the salt-free diet. He modified the salt-free regimen by emptying and washing out the stomach two and one-half hours after the chief meal. He also says that sodium phosphate or sodium bromid may be substituted for the chlorid in the food, at least to some extent.

From personal experience with a few patients on whom I carried out this method, I believe that the salt-free diet may be of great aid in the treatment of these cases.

The medicinal treatment must, in most cases, accompany all dietary treatment. This medicinal treatment in some cases is simple and in others more difficult. In those cases in which we have a straight chemical hyperacidity with no complications, such as hypersecretion, continued secretion or hyperesthesia, simple antacid treatment, with sodium bicarbonate and calcined magnesia, will often work wonders. I have the patients take this mixture only when the discomfort appears. Of late, I have used bismuth subcarbonate with the calcined magnesia in place of the sodium bicarbonate. My reason for this is that the action of the acid on sodium bicarbonate produces a large quantity of sodium chlorid which we wish to decrease.

In those cases complicated with hypersecretion, continued secretion or hyperesthesia, we must use the antacid treatment as before, but in addition to this, the use of oils, etc., as demulcents and the use of atropin or belladonna, anesthesin and bromids for their action on the gastric mucosa is recommended. In these cases when the stomach does not empty properly the use of Carlsbad salt before breakfast for flushing out the stomach and its action on the bowels should be used.

In 1908 Petri[4] found that hydrogen peroxid in rather large quantities (300 c.c. of 0.5 per cent. solution) on an empty stomach has a great power of lowering the acid content of the stomach. He recommended its use in hyperacidity.

Poly[5] of Würzburg in 1910 used hydrogen peroxid in forty cases of hyperacidity and recommends it highly. He recommends the large quantities used by Petri. It causes some nausea but reduces the acidity and the symptoms.

Hall[6] of Boston treated thirty patients and says that there is a lowered acidity, a gain in weight, and subsidence of the symptoms. He says that it is another aid to our treatment.

Winternitz[7] says that it reduces acidity, but not for long. He has discarded its use.

In 1909 I repeated Petri's work on normal stomachs and found his work true. I then tried the hydrogen peroxid in hyperacidity cases in order to test the following points:

First, What is the optimum concentration or dose to use? I found that small quantities, as 4 or 8 c.c., before meals, once or twice a day, had but little effect, the acidity being but slightly lowered. *Fifteen* c.c. began to have a decided effect on lowering the acidity, but the patients complain of nausea after taking this amount. I gradually increased the dose up to 50 c.c., which is Petri's amount. Petri's dose of 300 c.c. of 0.5 per cent. solution is decidedly unpleasant to the patient. Giving it in almond-water, as Poly suggested, lessens this trouble.

In the second place, I wished to determine whether the effect of the hydrogen peroxid was merely temporary or somewhat permanent. A patient was given a Boas-Ewald test breakfast and the total acidity, the free hydrochloric acid and the pepsin content determined. Before the evening meal 300 c.c. of a 0.5 per cent. solution was given the patient. The next morning a Boas-Ewald meal was given, using 300 c.c. of 0.5 per cent. peroxid instead of water. In nearly every case the free acid is greatly lowered, or even absent. The pepsin content suffers an almost parallel reduction. The patient was then given the peroxid before luncheon and before dinner. The next morning he was given the Boas-Ewald test breakfast with water. The free acid and pepsin content were generally normal or nearly so. This experiment was repeated many times and the results were always the same. From this experiment we learn that the action of the peroxid is only temporary and perhaps is effective only so long as it is in the stomach; in other words, its effect is purely local.

[7] Winternitz: Zur medikamentösen Therapie der Hyperazidität insbesonders über die Anwendung des Wasserstoffsuperoxyds, Deutsch. med. Wchnschr., 1911, xxxvii, 1390.

In the third place I tried to determine whether or not large doses of hydrogen peroxid might be injurious to the gastric mucosa when 300 c.c. of a 0.5 per cent. solution of peroxid is given for a long period of time. Large amounts of mucus are nearly always found in the stomach content when such large quantities of peroxid are given. This fact, together with the marked decrease or total absence of the free acid and pepsin, makes one think of the findings in atrophic gastritis. It might be possible for real injury to be produced by a long-continued use of such a substance. I carried out a number of experiments by giving the peroxid for some weeks. In two cases I continued the treatment for four weeks. In these persons it took days for the content to come back to the normal when the peroxid was discontinued. When it was given for only a day or two the return to normal was prompt. It is possible that a longer use would do lasting damage.

On account of the large amount of the peroxid required and its temporary effect, together with the unpleasant effect on the patient and the possibility of doing harm by a long-continued use, I have discarded its use as a therapeutic agent in hyperacidity.

Physical therapy, such as gastric lavage, is important. I am firmly convinced that washing out the stomach is of distinct value as an aid to the diet and the medicinal treatment in severe cases.

Of another form of physical therapy in hyperacidity, namely, exercise, I cannot speak too highly. I mean by this a graded, systematic course of exercise under the direct charge of the physician. Many of these patients come to us underfed, weak, nervous and flabby-muscled. They cannot do their daily task without almost complete exhaustion. Some other patients come to us fat, rotund, good livers and short of breath.

Both of these classes need a systematic course of exercise. These exercises harden muscles, improve the circulation, increase the appetite, and, in fact, often work wonders with our cases of hyperacidity.

These exercises properly given in the morning and in the evening before bedtime tend to employ the stomach, and thus a possible chemical irritation is removed.

The treatment of hyperacidity is a combination of diet, medicine and physical therapy. In most cases not one alone will do the work, but a painstaking, wise physician using all three equally, or emphasizing now one, now the other, will obtain results; and that is what we are after.

1402 South Grand Avenue.

The Price of Community Health.—Better community health is an issue between money and morals, between dollars and men; not always clearly perceived, frequently imperfectly understood, but nevertheless, when brought down to the last analysis, we find it too often to be ignorance and greed against health and intelligence. We know now that health is a purchasable commodity. We can prevent disease if we are willing to pay the price. Clean water, clean milk, clean streets, clean houses, clean schools, clean churches and clean people may all be had if the price is paid. It is to-day entirely up to the community whether it wishes to be clean and healthy or filthy and diseased. The method by which such rights can be secured is neither difficult nor obscure. The steps are simple and are applicable by the average layman or the village physician to the smallest village or rural community.—Eugene H. Porter, M.D., *Month. Bull. New York State Dept. Health.*

PRESENCE OF DIALYZABLE PRODUCTS REACTING TO ABDERHALDEN'S NINHYDRIN IN THE URINE OF PREGNANT WOMEN

A PRELIMINARY REPORT*

LOUIS M. WARFIELD, M.D.
MILWAUKEE, WIS.

In 1912 Abderhalden published results of experiments tending to show that in the blood-serum of pregnant animals and women there was a ferment which in the presence of specific placental tissue had the property of digesting the placental albumin. The products of this proteolytic digestion could be dialyzed through parchment and recognized by delicate tests for peptones and amino-acids. He used a substance, triketohydrindenhydrate, sold under the name of "ninhydrin," which enabled him to find not only peptones but also amino-acids. His work was taken up by observers especially in Germany and America. Many confirmatory results have been obtained as well as some results distinctly unfavorable.

In a series of cases at the Milwaukee County Hospital, our results were very contradictory. It occurred to us that if there were a specific ferment in the blood-serum which was elaborated to split up the products derived from the placenta, syncytium especially, there should be also in the blood-waste, products of the metabolic activity of the growing fetus. These substances had to leave the body by some route and the most logical route was the urinary excretion. These products should be peptones and amino-acids, they should dialyze out and one should then be able to find them by means of the ninhydrin reaction in the dialysate. It was found that actually such is the case. At first urine and pieces of boiled placenta were placed in one dialyzer, and urine alone in a second dialyzer. No difference was noted in the color reaction obtained with ninhydrin. Boiling the urine made no difference. Urine containing more than a trace of albumin boiled and filtered to clear of albumin and placed in the dialyzer showed in the reaction of the dialysate to ninhydrin no difference from the untreated specimen of urine.

The extreme difficulty of obtaining material enables me to report only seventeen cases; four were tested twice. Among these are two particularly suggestive cases, Nos. 4 and 13 in Table 1.

TABLE 1.—URINES, PREGNANCY

No.	Reaction	Albumin	Ninhydrin	Months Pregnant	Remarks
1	*	—	++++	9

* Acid. † Alkaline. + Present. — Absent. ± Trace.

---

* From the Medical Clinic and Laboratory of the Milwaukee County Hospital.

The first patient for five and a half months had shown a normal course. She suddenly developed headache, and the blood-pressure (systolic) was 160 mm. The dialysate tested with ninhydrin showed only a faint blue color. Eight days later she was quite well, blood-pressure 140 mm., and her physician obtained for me a second specimen. The dialysate showed a distinct increase in color and presumably an increase in the quantity of dialyzable proteolytic cleavage products. The other patient was about at term when she entered the hospital. One day there was a slight headache. The blood-pressure was 175 systolic, 120 diastolic. The ninhydrin reaction was slight. Three days later she was feeling quite well and the reaction was intense blue. The blood-pressure was the same. This suggests at once the possibility of forestalling toxemia of pregnancy by the test, and apparently suggests the retention of some fetal products due possibly to a temporary functional incapacity of the kidneys. As will be seen from Table 1, every case of pregnancy showed the presence of dialyzable substances in the urine except one. The pregnancy here was of only two months' duration. At four and a half months the reaction with ninhydrin gives an intense blue color. In order to show that in normal urine there are no dialyzable substances which give a positive test with ninhydrin, a number of urines from healthy persons were tested. These gave no color reaction. Solutions of urea were made and dialyzed. The dialysate in these cases showed no reaction.

In a few cases (all the material available) an attempt was made to determine for how long a time the urine contained these substances. In the involution of the uterus it is possible that waste protein cleavage-products are excreted by the body.

TABLE 2.—URINES, PUERPERIUM

No.	Reaction	Albumin	Ninhydrin	Days after Delivery
1	*	±	—	11
2	*	—	+	14
3	*	—		
	*	+	+++	8
			+	13
4	*	+	+	13
	*	±	—	16
5	*	±	—	16
	*	—	—	27
6	*	±	+	4
	*	—	—	16
7	*	±	+	5
	*	+	+	17

* Acid. + Present. — Absent. ± Trace.

Table 2 shows that the eleventh day was the earliest to show a negative reaction, while one still showed a faint reaction on the seventeenth day.

The material available to me is so scanty that this is put forth as a suggestive lead for large obstetric clinics to follow.

A SERUM REACTION AS AN AID IN THE DIAGNOSIS OF CANCER

OTTO LOWY, M.D.
Serologist for Beth Israel Hospital
NEWARK, N. J.

The discovery by Abderhalden of the presence of proteolytic ferments in the serum of pregnant women and his conclusion that it might be possible to find similar ferments in the serums of persons suffering from other conditions actuated me to look for a specific ferment in the serum of cancer patients.

The principle of the test is that of Abderhalden's test for pregnancy. The reaction depends on the presence of a specific ferment which has the power of digesting its corresponding albumin. In my experiments I use Schleich and Schnell diffusion thimbles No. 579, which have been tested for their permeability to peptones and impermeability to colloids, using only those permitting peptone and not colloids to pass. The cancer albumin is obtained by cutting up pieces of carcinoma of the breast and boiling them for half an hour, after which they are put into chloroform-water and kept on ice.

A small piece of the prepared cancer albumin is added to the dialyzing thimble with 2 c.c. of suspected serum. The thimble is then put into a glass cylinder containing about 10 c.c. of sterile distilled water. Thimble 2 contains serum alone and Thimble 3 contains cancer albumin and distilled water. Both these thimbles are put into cylinders with distilled water, same as No. 1. All of the serums, as well as the water surrounding them, are then covered with a layer of toluol and incubated for sixteen hours, at the end of which time 5 c.c. of distilled water of each cylinder is tested with ninhydrin for the presence of peptone, by boiling in a water bath for ten minutes.

If the tested serum be that of a cancer patient, Cylinder 1 will assume a deep violet color. Cylinders 2 and 3 should remain colorless. Should there be discoloration in Cylinders 2 and 3, the reaction must be discarded, as the serum was probably contaminated by bacteria, contained hemoglobin or amido-acids. If the serum is negative the water in all three cylinders should remain colorless.

If the reaction is positive, Tube 1 is retested against fresh serum, or if the test is negative, a retest is made against peptone, for the purpose of insuring against defective thimbles.

The blood used must be chemically as well as bacteriologically clean. About 10 c.c. of blood are required and should be obtained from one of the veins of the elbow in the same manner as for the Wassermann test. After obtaining the blood, great care must be used not to shake the vial containing it, as shaking is apt to dissolve some of the hemoglobin, and the presence of hemoglobin in the serum invalidates the test. Blood more than twenty-four hours old, or taken after meals, cannot be used for the test.

Through the kindness of Drs. E. J. Ill, George N. Waite, L. L. Davidson, E. Mautner, I. Gluckman and others I have been able to examine the serums of sixty-one cases, consisting of the following: 19 cases of carcinoma, 7 of diabetes, 7 of syphilis, 4 of ulcer of the stomach, 2 of pregnancy, 1 of extra-uterine pregnancy, 1 of furunculosis, 2 of fibroids, 1 of lipoma, 1 of chronic appendicitis, 1 of cholecystitis, 3 of carcinoma (postoperative) and five other cases the results of which were confusing owing to the age of the serum. All of the cancer cases gave a positive reaction. The three postoperative cases in which the patients operated on two, four and five years ago, and that do not now give any clinical symptoms of recurrence, gave negative reactions. In this connection it is interesting to note that one of these patients was operated on by Dr. George N. Waite five years ago for carcinoma of the breast. The patient was again operated on two weeks ago for an extra-uterine pregnancy. In my examination the serum gave a positive reaction for pregnancy and negative for cancer. In two cases of cancer of the breast, in one of which the patient was operated on two and the other nine months ago, the reaction was still positive.

All the other cases gave negative reactions with the exceptions of the benign tumor of the breast, one case of fibroid and one case of diabetes. I believe that the erroneous findings in these cases were due to faulty technic which I am now trying to eliminate.

All cases of carcinoma examined were cases in which clinical and microscopic evidence of malignancy were present.

In view of these findings the following questions present themselves:

1. Is the reaction present in all cases of carcinoma?
2. What other, if any, conditions will give positive reactions?
3. How early will this test give a positive reaction?
4. How soon does the reaction disappear after the operation?
5. Will reappearance of the reaction after operation mean recurrence?
6. Will persistence of the reaction after operation have any bearing on the prognosis?
7. Will this reaction prove a precancerous stage?

In conclusion I wish to say that even with this limited number of tests and in their primitive state, I have found a proteolytic ferment in the blood of cancer patients. Whether or not this ferment is specific and constant I am unable to say at this time. Nevertheless, an analysis of some of my cases shows that in at least three undoubted cases of cancer in which the patients were operated on the reactions were negative after a lapse of years, which would indicate that with the removal of the growth the specific ferment is not needed in the blood and disappears. Two other cases which still give positive reactions are of no significance at this time as not all the cancer tissue may have been removed by operation, or time enough may not have elapsed for the ferment to disappear.

I think that we would be justified in using this test for obscure stomach cases, and if the test should prove of specific value periodic examination of women approaching the menopause would be the means of saving the lives of untold women.

549 High Street.

INVESTIGATION OF THE PREVALENCE OF MALARIAL FEVERS IN THE UNITED STATES BY THE UNITED STATES PUBLIC HEALTH SERVICE

R. H. VON EZDORF, M.D.
Surgeon, U. S. Public Health Service
MOBILE, ALA.

Under orders of the Surgeon-General of the United States Public Health Service, dated Feb. 28, 1912, I was directed to make a study of the prevalence of malarial fevers in the state of Alabama; and July 8, 1913, the states of Arkansas, Mississippi, Georgia, Florida, South Carolina and later North Carolina were included in this work. A visit was made to the officers of the boards of health of all the states in which the studies were to be made, and their cooperation was obtained.

The work outlined in the first order Feb. 28, 1912, covered the following points:

1. The localities in which malarial fever is endemic.
2. The relative prevalence of the disease in the various localities.
3. The types of malarial infection present in the several localities.
4. The distribution of anopheline mosquitoes.
5. The relative prevalence of mosquitoes in the several localities, with special reference to the anophelines.

This work of investigation was pursued according to the following methods:

I. STATISTICAL INVESTIGATION

Circular postal cards with attached reply cards were sent out to all physicians in the states of Alabama, Arkansas, Florida, Georgia, Mississippi and South Carolina, calling for information for the months of August, September and October, 1913, which was to bear mainly on the morbidity of the disease, the species of mosquitoes, their breeding-places, and the prophylatic measures adopted in each place. The replies received have been filed according to counties. These are now being tabulated and will form part of a report. This work of securing information will be continued during the coming year, with a view to obtaining not only the geographic distribution and prevalence of the disease, but also its seasonal prevalence, and will eventually be made to cover the entire United States.

A number of letters were received from physicians which gave more detailed information than the postal card called for, and many letters were received asking for general information on the subject of malaria.

The tabulations will show in each county for each month: the number of physicians reporting; number of towns, cities or places represented; number of patients, by color, treated for malaria; types of infection; types confirmed microscopically; number of physicians using the microscope; number of cases occurring in children under the age of 15; number of chronic cases; presence of mosquitoes and the species, and prophylactic measures adopted.

II. TYPES OF MALARIAL INFECTION

In order to ascertain definitely the types of malaria, it was determined to make blood examinations from both active and chronic cases. A circular letter was addressed to a number of physicians in each county in the state of Alabama (Mobile County excepted), requesting them to send blood-smears from active and chronic cases, and stating that slides, slide-boxes, history blanks calling for names, age, sex, color, nativity, address, length of residence, previous history of malaria, remarks and date, and franks for returning such slides and information, would be furnished. The foregoing material and a letter of instruction for making thin and thick blood-smears was sent to those physicians who replied favorably.

Accordingly, it was expected that blood-smears from every county in the state would be obtained; but comparatively few physicians responded, and only eleven counties of the sixty-six have been heard from. Those physicians who sent in specimens were immediately informed of the result of the examination. Tertian and estivo-autumnal types were confirmed, and not a single quartan specimen was submitted.

III. DISTRIBUTION OF ANOPHELES MOSQUITOES

Physicians in every county in Alabama were asked by circular letter to send in specimens of mosquitoes, particularly anopheles, in vials and mailing cases which, with franks for return, were furnished.

The specimens submitted were of *Culex, Aëdes calopus, Anopheles quadrimaculatus, A. punctipennis, A. crucians, Megarrhinus rutilus,* Coq. (classified by Dr. L. O. Howard, Chief of the Bureau of Entomology, Department of Agriculture), and *Psorophora ciliata.*

IV. SURVEYS AND MALARIAL INDEX

Surveys this year were made in selected localities in Arkansas, Alabama and North Carolina, and a malarial index was made by the collection of blood specimens from all persons who submitted themselves for examination. The surveys included a study of the geographic and climatic conditions of the locality, the social, hygienic and economic conditions of the community and the industries. The breeding-places of the anopheles were searched for and their breeding conditions were studied. The health officer and officials were informed of the findings in each place visited, and measures for the eradication of the breeding-places were advised. Some interesting observations were made, particularly of the fact that the mosquitoes did not breed in ditches where waste, such as dye-water or coal-gas water was discharged, and that such discharges might be diverted to the advantage of other places in which mosquitoes were breeding.

The importance of making malaria surveys is becoming of interest to the public, especially in places where large industries are impounding water for power and for purposes of public supply. On this account, condemnation proceedings and suits for damages are being filed in the courts, and when the reasons for legal action have been sought, those who bring suit have usually been found to be ignorant of the method of transmission of the disease; while the breeding-places of anopheles are ordinarily to be found within a short distance of the homes. Particularly is this true in rural districts. The impounded waters are, as a rule, free from breeding mosquitoes, but occasionally a small breeding-place, which might serve as a constant source of supply of mosquitoes, may be found on the banks. These are, generally, far removed from any homes. In some instances, undoubtedly, the impounding of waters has been beneficial.

MALARIAL INDEX

Blood-smears were obtained from 3,602 persons living in seven places in North Carolina. Three hundred and thirty-eight of these were secured through the assistance of Drs. Pridgen, Leonard and Maynard, at Knott's Island; 802 from five places in Arkansas, 52 of them through the assistance of Dr. H. K. Thibault at Scott, and 664 from four places in Alabama, the total being 5,068. There were also 67 obtained with the assistance of Dr. Boyd, city health officer at Columbia, South Carolina.

One thick and one thin blood-smear was made and a history was obtained from each person examined. The blood-smears were inspected to determine the presence of the parasite, the type of infection, the blood changes which might be attributable to malarial infection, such as leukopenia, the presence of pigment normoblasts, increase of mononuclear leukocytes and poikilocytosis. Any other blood changes were noted, as eosinophilia, and other types of infection such as are shown by the presence of filaria or *Spirochaeta obermeieri.* The technic employed has been greatly simplified for expeditious work, and has been described and submitted for publication in the Public Health Reports.

V. EDUCATIONAL WORK

Under the auspices of the state boards of health, arrangements were made for delivering public addresses and lectures at schools on the subject of malarial fevers, their method of spread and prevention. Lantern-slides were sometimes used. Specimens of larvae and pupae collected in the locality were exhibited to show the different species and demonstrations were given to show how anopheles may be identified. The local conditions were invariably discussed. In several places in North Carolina classes of schoolchildren of the higher grades were taken out on a search for mosquito breeding-places and taught to distinguish the anopheles larvae. In one place these pupils were required to write a composition on the subject of mosquitoes, their characteristics in different stages of development, and the identification of the anopheles.

The Public Health Service is preparing exhibits on the subject of mosquitoes and malaria to be used in these lectures, and photographs are being made and collected which will be reproduced in lantern-slides.

VI. COMMUNITY ANTIMALARIAL WORK

The application of different methods to be adopted were discussed during the lectures, with special reference to local conditions. Drainage, screening and the use of quinin were advised, and the practical and economic benefits to be derived were set forth and illustrated by examples derived from the adoption of these measures in different portions of this country.

The greatest difficulty lies in the question of cost and funds. On this account the service is enlarging the staff of workers in order that proper measures and estimates may be submitted for consideration, when a community desires to undertake the work of control or eradication. The supervision of such work, would, of course, be undertaken only in cooperation with the state boards of health. There are now two communities in North Carolina which are planning to do this work under the direction of the state board of health.

VII. PERSONNEL

An office and laboratory have been established at Mobile, Alabama, where this work is being conducted. The personnel comprises one surgeon, one assistant surgeon, two technical assistants, one biologist and two clerks. Similar work is being conducted for the state of Louisiana at New Orleans, under the direction of Surgeon J. H. White and one assistant surgeon.

Senior Surgeon H. R. Carter of Baltimore, Maryland, has also been engaged in making surveys in North Carolina, and is devoting much time to this subject.

Egyptian Medicine.—Herodotus declares Egypt to be the healthiest of countries, but filled with physicians of whom "one treats only the diseases of the eye, another those of the head, the teeth, the abdomen or the internal organs." Diodorus says that Egyptian physicians looked on excessive consumption of food as the main cause of disease, cured chiefly through fasting, emetics and purgatives and were under obligation to treat soldiers and travelers without fee. The same author remarks that the unsuccessful issue of a course of treatment conducted on recognized and prescribed lines was not to be laid to the blame of the physicians, whereas independent procedure, going outside the bounds of tradition, carried the death penalty with it, in case of a fatal result. According to Clement of Alexandria, the medical science of the Egyptians was contained in the forty-two Hermetic books whose authorship is ascribed to the god Thot (Hermes of the Greeks).—Neuberger, History of Medicine.

VALUE OF ROENTGEN ANALYSIS OF GASTRO-INTESTINAL TRACT IN SOME TYPES OF SO-CALLED FUNCTIONAL NERVOUS DISORDERS

A PRELIMINARY REPORT *

L. PIERCE CLARK, M.D.
AND
ARCHIBALD H. BUSBY, M.D.
NEW YORK

We have limited the type of cases to that of genuine epilepsy solely in order that the nervous type of disorder under study may be exact and without question. Exact analysis of the digestion of the epileptic has been attempted for years. It matters little, as to the importance of such study, whether one holds that the defective digestion in epilepsy is a result or a cause of the nervous disorder. Definite knowledge of whatever defect in digestion obtains in an epileptic is worthy of our best efforts. Any method of investigation which will throw light on the subject, therefore, should be welcomed.

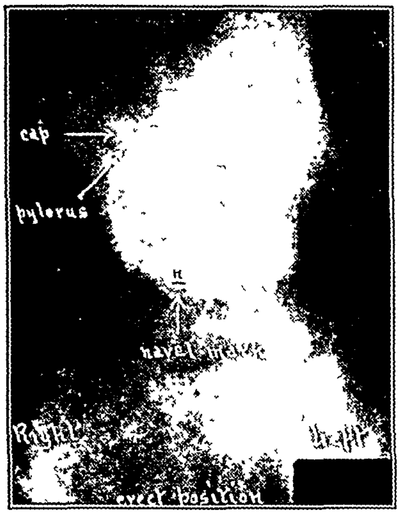

Fig 1.—One type of normal position of stomach—erect.

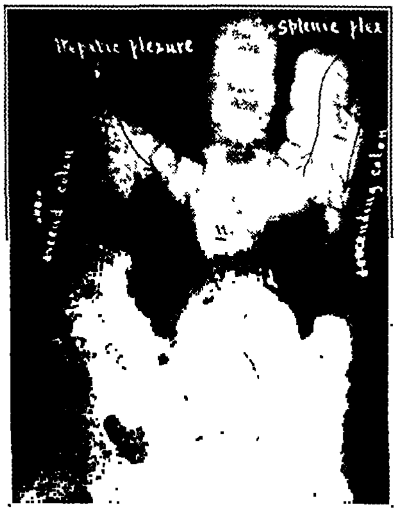

Fig. 2.—One type of normal position of colon

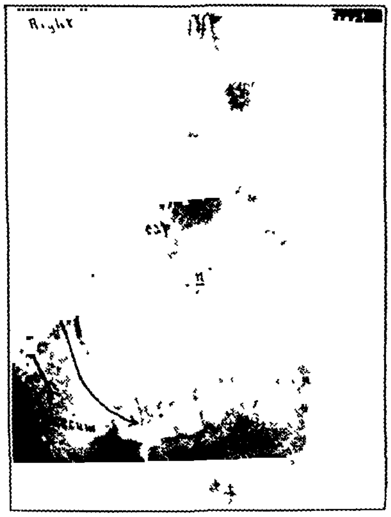

Fig. 3.—Case 2. Gastroptosis with ptosis of hepatic flexure and transverse colon.

For many years it has been supposed that constipation, intestinal catarrh and any of the many forms of mucomembranous colitis found in epileptics were due to a secretory defect of some kind, or that there was an inherent defect in peristalsis; but only recently have genuine attempts been made to analyze precisely by means of the Roentgen ray some of the mechanical or dynamic gastro-intestinal defects in epileptics. Here and there one finds a case so analyzed treated surgically with varying results reported. At the outset we wish to disclaim that we have approached our subject with any particular bias as to curing the patient of epilepsy. The analysis was not undertaken with the idea of deciding whether or not a surgical cure of the intestinal defect and even the epilepsy itself could be accomplished, but the study was made solely to determine what mechanical defects obtain in fairly classic cases of epileptics suffering from long-standing and obscure indigestion.

It is common knowledge that many have striven to translate supposed mechanical defects in the gastro-intestinal tube into terms of so-called intestinal auto-intoxication. The authors of such attempts deal with theories solely, assume chemical interpretations of metabolism which have little or no clinical proof, or push their deductions to unwarrantable conclusions. It would seem reasonable that by means of the Roentgen ray one might determine the points or parts most affected in the gastro-intestinal tract, follow this determination by dietetic, hygienic and other special medicaments of massage, electricity and like remedies, and overcome the defective state of digestion of epileptics, thus bettering their general health and perhaps modifying favorably the course of the convulsive disorder itself. Subsequent Roentgen analysis in the individual case might prove exactly what had taken place by such treatment. Even though physical and hygienic measures of treatment be found inefficacious, such a system of study and therapy might still find legitimate use in conservative practice until one determined on more drastic surgical relief.

With the foregoing view in mind, one of us (Clark) proposed a Roentgen analysis of a small but select material to determine the value of the procedure for diagnostic and therapeutic purposes. Ten cases were therefore selected from private practice in which the epileptic convulsions seemed most dependent on or bore some relation to a digestive disorder. In all, the premonitory symptoms of extreme constipation, furred tongue, headache, malaise, gaseous fermentation in stomach and intestines and mucous and membranous discharges from the bowels had been chronic before attacks, and in many cases existed more or less throughout the interparoxysmal state. Both sexes, of ages varying from 10 to 48 years, were under study.

TECHNIC

The examinations in this series of cases were made in the following manner: After fourteen hours of fasting, a meal was given the patient consisting of 2 ounces of bismuth subcarbonate in 12 ounces of buttermilk, and the stomach exposures were immediately made in both the prone and the erect positions. Nothing else was

---

* Read at the Annual Meeting of the American Neurological Association, Washington, May 6, 1913.

taken by the stomach until the six-hour period was made for gastric retention. The patient was then allowed to take regular meals. At twenty-four hours, the examination was made also in the prone and erect positions, and later at forty-eight hours if possible. Most of these patients felt so miserable at the end of twenty-four hours that it was thought wise not to continue further. One of us (Busby) personally has taken large amounts of bismuth without feeling any ill effects.

The first consideration is, What is the normal appearance of the gastro-intestinal tract as revealed by roentgenoscopy? We must not be too willing to digress from the text-books, for they are the results of conclusive work made on the gastro-intestinal tract normal and *in situ*. One can readily understand that, in the erect position of man, the filled, functionating tract would by gravitation severely test the efficiency of this more or less poorly supported part of the body. Because the roentgenographic examinations show a greater number of variations than we have been cognizant of heretofore we must not infer that they are any the less abnormal. Mechanical difficulties are made possible and it is the active, functionating gastro-intestinal tract with which we have to deal.

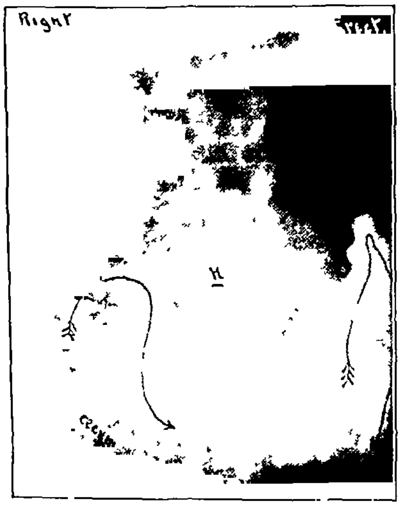

Fig. 4.—Case 4. Coloptosis.

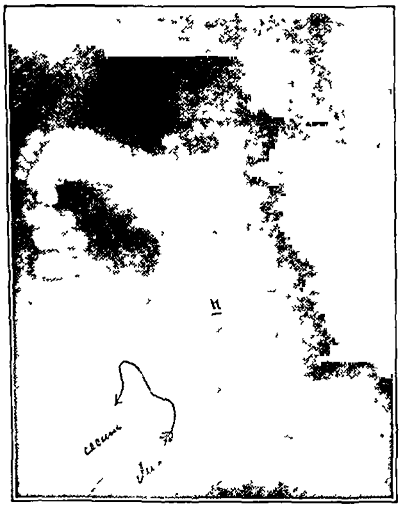

Fig. 5.—Case 6 Ileac stasis at twenty-four hours; prone.

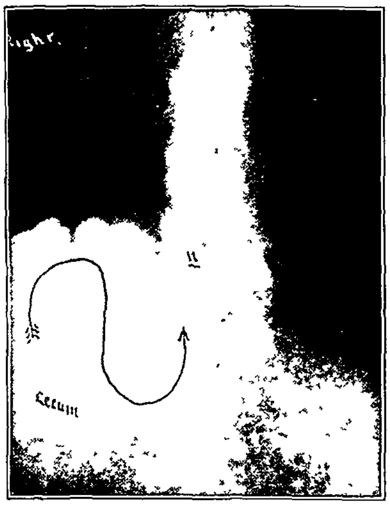

Fig 6—Case 7. Ptosis of hepatic flexure and ascending colon; twenty-four hours prone.

In regard to the weight of the bismuth given, 2 or 4 ounces would not be expected to make any material difference when one stops to consider the weight of an ordinary meal. The next consideration is, How many of the apparently normal cases which we examine for controls are really normal? For it is thought that many of these postural conditions date back many years, even so far as childhood, and exist for long periods before causing trouble. It is also perfectly true that some can exist indefinitely without causing symptoms that are diagnosable as a disease entity. Then again, congenital malformations may be found. Experience has taught us that a difference of from 2 to 3 inches may be allowed between the prone and erect positions.

Two roentgenograms, in which the stomach and colon appear to be as nearly the text-book type as possible, are given to contrast those in the other pathologic cases.[1] Figure 1 shows one type of normal stomach, erect position. In Figure 2 one type of normal colon is shown by injection.

The Roentgen findings in ten cases of epilepsy are as follows:

CASE 1.—G. R., female, single, aged 17, has had attacks for five and one-half years. Roentgenoscopy with the patient in the prone position reveals the stomach normal in size, position and outline with a plain pylorus and good cap; in the erect position a slight ptosis is revealed with the pylorus and cap hazy. Six hours later roentgenoscopy reveals considerable gastric retention with good cap. There are patches of bismuth in the small intestine with a larger quantity in the ileum and ascending colon. The cecum is very low. At the twenty-four-hour period, roentgenoscopy reveals the hepatic and splenic flexures in good position with a large amount of bismuth in the low cecum and in the ascending colon. Bismuth also appears in the sigmoid and rectum. At the twenty-four-hour interval roentgenoscopy in the erect position reveals a slight dropping of the flexures, not abnormal. There is some gas in each. The cecum is again seen very low.

Summary.—The stomach retention would appear to be the result of atonia rather than obstruction. Some ptosis is usually found with atonia. The low cecum which is apt to retain food for a long period may very possibly cause sigmoid interference when filled.

CASE 2.—A. D., female, single, aged 22, has had attacks for six and one-half years. Roentgenoscopy with the patient in the prone position reveals a large stomach moderately low and rather atonic in shape with a normal pylorus and large cap; the erect position shows better the atonic shape with a considerable gastroptosis (Fig. 3). At the seven-hour period roentgenoscopy shows no gastric retention. At the twenty-four-hour period roentgenoscopy reveals both flexures low with a low transverse colon and a distinct looping at the hepatic flexure.

Summary.—This case shows a marked gastroptosis. There is a coloptosis of moderate degree.

CASE 3.—J. L. D., male, married, aged 46, has had attacks for seven years. Roentgenoscopy with the patient in the prone position reveals the stomach negative in shape, size, and normal position. Six hours later roentgenoscopy shows no gastric retention. At the twenty-four-hour interval, roentgenoscopy reveals a low hepatic flexure with the transverse colon well within the pelvis. At the forty-eight-hour period the bismuth is shown still in the low hepatic flexure and transverse colon.

Summary—This case shows a ptosis of the hepatic flexure and transverse colon.

---

[1] We should prefer to show each phase of the individual cases by illustration; but owing to limited space, only a few roentgenograms are given.

Case 4.—A. R., male, single, aged 37, has had attacks for three years. Roentgenoscopy with the patient in the prone position reveals a ptosis of moderate degree. The contour is negative except the pylorus, but other roentgenograms show that this is also negative; in the erect position there is a gastroptosis of marked degree. The stomach in this position gives evidence in its shape of being atonic. At the seven-hour period, roentgenoscopy reveals a slight gastric retention. Bismuth is seen in the ascending and transverse colon. At the twenty-four-hour interval bismuth appears in the entire colon and the flexures are in normal position. Roentgenoscopy in the erect position shows a marked coloptosis with the flexures very low (Fig. 4).

Summary.—This case demonstrates a marked visceroptosis.

Case 5.—W. M., male, single, aged 25, has had attacks for two and one-half years. Roentgenoscopy with the patient in the prone position reveals the stomach in normal position with negative pylorus and cap; the size is rather large and suggests atonia. Seven hours later there is a slight amount of gastric retention with bismuth in the ileum, ascending and transverse colon, and also a looping at the hepatic flexure. At the twenty-four-hour interval the entire colon is seen with more bismuth in the ascending portion. The ragged appearance at the hepatic flexure suggests adhesions. At the twenty-four-hour interval, roentgenoscopy in the erect position reveals a slight dropping of both the hepatic and splenic flexures. By rectal injection the splenic flexure is replaced in its normal position by the force of the injection and it also brings out the loop at the hepatic flexure with its ragged appearance.

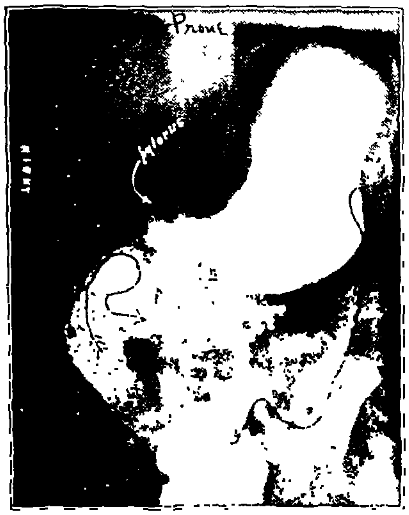

Fig. 7.—Case 8. Ptosis and looping of hepatic flexure. Ragged pylorus.

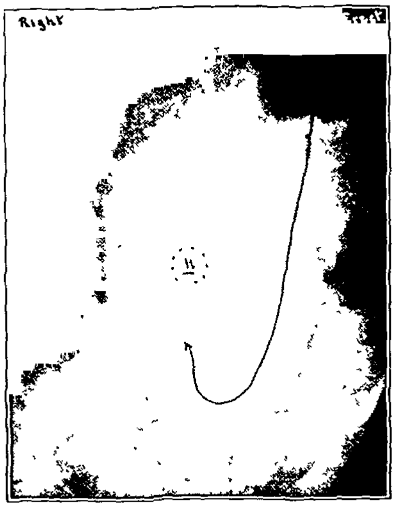

Fig. 8.—Case 9. Gastroptosis.

Summary.—This case shows slight gastric atonia with indications of trouble at the hepatic flexure. We also consider it a case of moderate coloptosis.

Case 6.—Mrs. D. M., married, aged 45, has had attacks for two years. Roentgenoscopy with the patient in the prone position reveals the stomach negative in shape, size and normal position; in the erect position a dropping which is hardly more than normal is revealed. Six hours later, roentgenoscopy reveals no gastric retention, with busmuth in the ascending and part of the descending colon. At the twenty-four-hour period, roentgenoscopy reveals decided ileac stasis which should never appear at this late period. Bismuth is shown in the ileum, ascending colon and part of the transverse colon (Fig. 5). At the forty-eight-hour interval a normal colon is seen with the exception of a long transverse portion. At the forty-eight-hour interval roentgenoscopy in the erect position reveals a dropping of the hepatic flexure and transverse colon with no apparent looping.

Summary.—This case shows a definite ileac stasis with a ptosis of the hepatic flexure.

Case 7.—Mrs. C. J., married, aged 48, has had attacks for ten years. Roentgenoscopy with the patient in the prone position reveals the stomach long, moderately low, a negative pylorus and a very high duodenum; in the erect position, this organ is converted into more of the water-trap variety; it is moderately low with the duodenum again remaining in the same high fixed position as in the prone position. Twenty-four hours later the prone position reveals the ascending colon ptosed on itself to such a degree that the hepatic flexure is in the pelvis. At the twenty-four-hour interval the erect position reveals the entire bismuth accumulated in this ptosed portion of the colon, showing well how a marked degree of stasis may occur here (Fig. 6). At the forty-eight-hour interval, roentgenoscopy reveals the colon attempting to straighten itself out. The cecum is *in situ*, but the entire ascending colon, hepatic flexure and part of the transverse colon are in the pelvis.

Summary.—This case shows possible gastric trouble with definite ptosis of the first half of the colon and a fairly high splenic flexure.

Case 8.—J. R., female, aged 10, has had attacks six and one-half years. Roentgenoscopy with the patient in the prone position reveals the stomach rather large for a child, and the pylorus is ragged in appearance, which may be due to thickening, spasm or adhesions. This peculiar pylorus is evident in all of the exposures made. There is a ptosis and looping at the hepatic flexures; in the erect position only a comparative dropping and the ragged pylorus are again evident (Fig. 7). Seven hours later, roentgenoscopy reveals a moderate amount of gastric retention, with bismuth in the ileum, ascending and transverse colon. At the twenty-four-hour interval bismuth is revealed in the ascending and transverse colon with a rather low hepatic flexure. The splenic flexure is situated well up as shown by gas. There is bismuth in the sigmoid and rectum. At the forty-eight-hour interval, roentgenoscopy reveals bismuth in the ascending and transverse colon with gas in the splenic flexure and also a large amount in the dilated sigmoid and rectum. This shows how the low transverse colon may cling on the high splenic flexure which here is filled with gas.

Summary.—The gastric retention rather suggests an obstructive interference of moderate degree on account of the peculiar pylorus. The position is good from a point of drainage. The pylorus can be watched in future examinations. The fact that the bismuth remains in the low ascending and transverse colon would suggest a valvular action in the high splenic flexure due to lack of muscular tone and dragging on this fixed point. The sigmoid and rectum show atonia and dilatation.

Case 9.—C. D., female, single, aged 25, has had attacks for eight years. Roentgenoscopy with the patient in the prone position reveals a moderate gastroptosis and a very large stomach, negative in outline; in the erect position, a marked gastroptosis is shown (Fig. 8). At the six-hour period there is no gastric retention. At the twenty-four-hour period roentgenoscopy in the prone position shows a marked coloptosis. At the twenty-four-hour period the erect position shows a marked coloptosis in which the colon and flexures appear to be within the pelvis.

Summary.—This case shows a marked gastroptosis and coloptosis.

Case 10.—H. V. L., male, single, aged 34, has had attacks for sixteen years. Roentgenoscopy with the patient in the prone position reveals the stomach situated high, horizontal and negative in outline and size; in the erect position, a negative stomach is revealed only relatively lower than in the prone position. At the six-hour period roentgenoscopy reveals no gastric retention in the prone position. At the twenty-four-hour period the colon is in normal position and the flexures well fixed. There is a large cecum, a narrowing of the ascending colon and a dilatation of the colon at the hepatic flexure. Roentgenoscopy in the erect position at the twenty-four-hour interval shows that the position of the colon is well maintained.

Summary.—This case shows a large cecum, a dilatation at the hepatic flexure and a narrowing of nearly the entire length of the ascending colon, which has every appearance of adhesion (Fig. 15).

From the foregoing study it is obvious that some form of abnormal position of the various parts of the gastro-intestinal tract is present in every case examined.

We are not in a position to explain the genesis of these defects, nor do we believe that the various theories advanced for their interpretation in the general field, exclusive of their presence in nervous subjects, are convincing, although those advanced by Hertz and Lane appear to be most plausible. We are certain, however, that it is the part of good internal medicine to reckon with the facts shown both in diagnosis and therapy.

In the several months' treatment subsequent to these roentgenoscopies, an intensive and more direct application of hygienic measures of massage and exercise therapy and other simple plans of treatment has been inaugurated to fit the special defect of each case, and marked physical and neurologic improvements have taken place not noted in a previous period without such therapy. To many internists and surgeons it may seem altogether unreasonable for us to expect that even an approximately normal digestion should obtain in such a case as that of Mrs. C. J., in whom the hepatic flexure is so greatly ptosed. Before our special treatment was undertaken in this case, however, natural movements of the bowels occurred but once a week, whereas now, after about three months' treatment, normal movements occur almost daily. After all, the functional test of digestive efficiency is the final proof. In the course of a year we hope to furnish Roentgen-ray controls, so that we may note whether or not the actual positions of the viscera have changed corresponding to the improved functioning already noted.

Our final conclusion is that Roentgen analysis of the defective digestive of epileptics is of both diagnostic and therapeutic value, and is an excellent supplement to the chemical and bacteriologic tests already in use, which form such a prominent part in any comprehensive hygienic plan of treatment in a stubborn nervous disorder of this kind.

84 East Fifty-Sixth Street—103 East Sixty-First Street.

Street Accidents in 1913.—The report of the National Highways Protective Association shows that during the month of December 25 persons were killed by automobiles in New York City. Of these 12 were children under 16 years of age. This makes a total of 302 killed by automobiles in this city in 1913, of which 149 were children. The number killed in 1912 was 221, of whom 103 were children. Six persons were killed last month by trolleys, against 13 for December, 1912, making a total of such accidents for the year of 106 as against 134 for 1912. In the state, outside the city, 9 persons were killed by automobiles during the month of December, 1913, as compared with 13 for 1912. This makes a total of 150 deaths by automobiles in the state, 79 by trolley and 32 by wagons, as compared with 127 by automobiles, 79 by trolleys and 28 by wagons for 1912. The National Highways Protective Association announces that it has started a campaign for the continuous enforcement, in a reasonable way, of the traffic ordinances.

POSSIBILITIES IN THE ROUTINE PRACTICE OF A SMALL HOSPITAL *

HERBERT C. COLE, M.D.
BOGALUSA, LA.

A small hospital, isolated by hundreds of miles from the great centers, will lend itself to modern, up-to-date routine practice, under properly applied technic and rigid discipline, if there is the ambition and the administrative faculty in control of the institution's activities. There need not be vast expenditure or elaborate equipment.

For many years the great manufacturing interests of our country have been perplexed in their efforts to operate profitably and at the same time conserve the combined interest of their stockholders and employees. During that time manufacturing enterprises throughout the country have destroyed thousands of human lives by not supplying adequate medical and surgical attention to their men. Formerly the sick and maimed were replaced with new human material while the disabled were turned loose, to be cared for by the state in which they lived, or migrated. As a result of these practices many thousands of useful persons have been incapacitated, a spirit of resentment for corporation employment has been engendered, dissatisfaction leading to dissension, strife and bloodshed has developed, and the progress of our natural resources dampened.

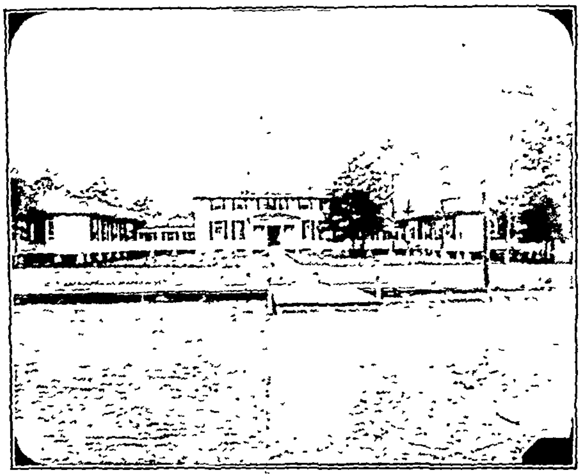

Fig. 1.—Front view of hospital.

Emanating from the ever-dominant principle of greatest utility to be derived from conservation of energy and material and the preservation of health and happiness, the great business interests operating through the Great Southern Lumber Company and the New Orleans Great Northern Railroad, two allied corporations operating in Louisiana, considered in their plans for economy the value of human life. From investigations into this item of their operating economy, and in justice to humanity, plans were evolved by which there could be furnished by mutual cooperation and without great expense or inconvenience, adequate medical and surgical protection to their employees.

For business enterprises of this kind to prosper it is essential that every economic problem be solved. It is obviously necessary for the health of the community to be preserved; it is imperative that epidemic outbreaks be quelled and the general health of the community kept at its highest standard. Without adequate facilities and competent services this is impossible. Appreciating these facts, the companies of which I speak, although isolated by hundreds of miles from the great centers, and in the midst of what was but a few years ago a vast pine forest, have erected a thoroughly modern hospital, equipped with every convenience and the equal of the better class of institutions of its kind in the cities. Under properly applied technic and rigid discipline, this hospital has loaned itself to an up-to-date routine practice such as you rarely see outside the great centers. As evidenced by the cost of construction and maintenance, there need not be vast expenditure or elaborate equipment. Constructed at an expense of $41,000, including equipment, and maintained at an annual expense of $30,000, including physicians', superintendent's and nurses' salaries, this institution furnishes protection for two allied corporations representing investments of over nineteen million dollars and numbering from eight to nine thousand employees. Isolated as it is by the geographical location of the natural resources which these corporations are developing, and in the midst of which the plant is established, it becomes necessary that adequate and efficient medical services be supplied.

---

* Read in the Section on Hospitals of the American Medical Association, at the Sixty-Fourth Annual Session held at Minneapolis, June, 1913.

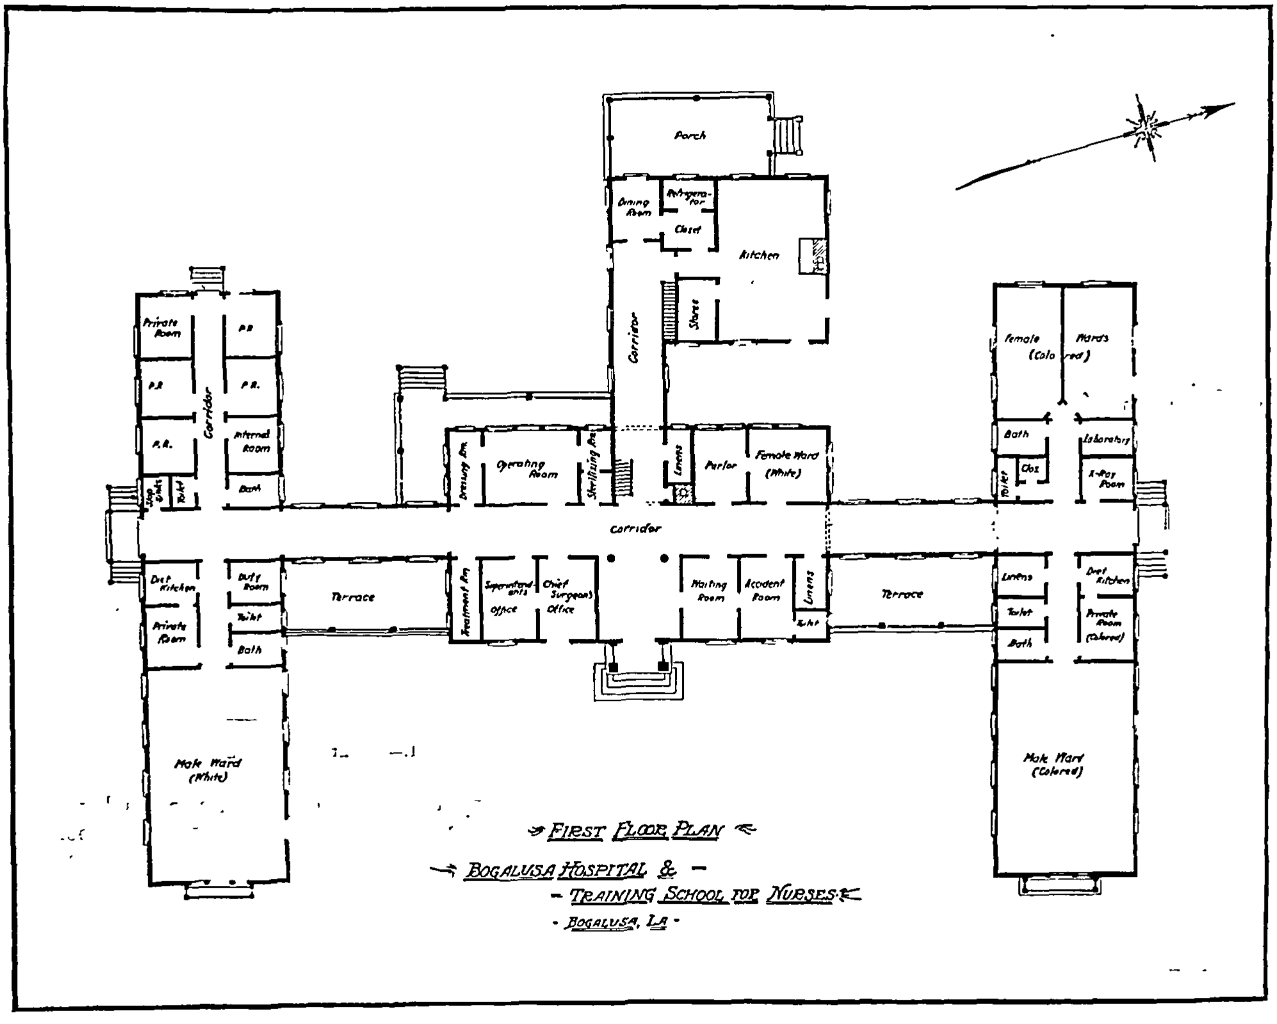

Fig. 2.—First floor plan.

While it is true that among some members of the medical profession there prevails a spirit against corporation employment of physicians, arguments to that effect having been advanced, yet I dare say that in the vast majority of such instances the argument was submitted without due appreciation of conditions as they are. It is a veritable fact that those who follow corporation employment, allowing for exceptions only in the case of officials and clerical employees, with a small percentage of the better class of laborer, are either financially unable to supply themselves with adequate medical and surgical protection, or do not pay for these without compulsion. Thus it is that in order for the health of such a community as this to be conserved and proper care taken of the sick and injured, it is absolutely necessary that something of a cooperative system be followed. Appreciating these facts, the great interests of which I speak evolved the following plan:

PLAN OF A HOSPITAL FOR FIFTY PATIENTS

A hospital designed to accommodate fifty patients was constructed according to the following scheme: A main building of two stories with two wings intersected by ells, the latter having one story each, and a third wing of one story extending backward from the main building. All sections are connected by means of hallways meeting at the main entrance, and all is under the same roof. In the main building, first floor, provision is made for white and colored people, separate waiting rooms, each opening into a large room arranged to meet the double requirements of clinic and consultation-room. Aside from this, we have rooms for the chief surgeon's private office, the superintendent's private office, and a treatment-room utilized also for operating-room. A main operating-room connects with a sterilizing-room, preparatory-room and instrument-room. In addition, this section also supplies space occupied by nurses' parlor and lecture-room, and a ward with three beds for white females. Each wing of the hospital leads from the main building and is occupied by a large hallway communicating with sun galleries on both sides. At the end each wing is crossed by the ells, which are occupied by hallways communicating on one end with a large ward of fifteen beds for white males, seven private rooms for white patients and accessory rooms utilized separately for record-room, diet-kitchen, bath-room, laboratories and house physician's room, with accessory bath and water-closet. The other end is divided into three wards, two for colored females, accommodating ten patients, and one large ward accommodating fifteen colored male patients, record-room, diet-kitchen, water-closet and bath, same as other side, but in addition one private room for colored patients requiring isolation. On this end, also, we have the Roentgen-ray and electrical department and laboratories for clinical microscopy and pathology.

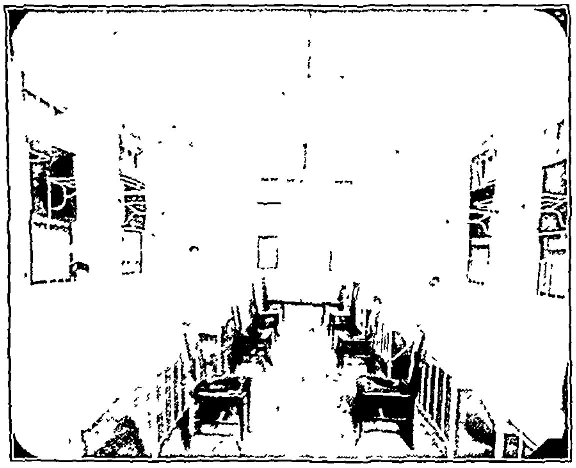

Fig. 3.—White male ward.

Extending back of the main building we have space for kitchens, pantries, store-rooms and dining-room for house physician, superintendent and nurses, and one additional for the servants. This section, like those previously described, communicates with the main building by means of a large hallway.

Upstairs over the main building, is utilized for superintendent's apartments and nurses' home. Accompanying are illustrations of the hospital and a plan of its general arrangement.

SYSTEM OF MANAGEMENT

Having given you an idea of our general equipment with its convenience, let me now briefly discuss our general system of management.

Relation of Physician to Patient.—The medical staff is composed of four doctors, all trained according to present standards, who rank according to the following order: a chief surgeon, a first assistant surgeon and a house physician. The duties of each as outlined in routine practice of the institution are as follows: Regular hours of service at the hospital are observed and arrangements are such that at no time, day or night, is the hospital without a doctor. Office hours are from 8 a. m. to 8 p. m., arranged so that each doctor fills an hour in the morning and an hour during the afternoon or evening. During each doctor's office hour he is responsible for the affairs of the institution. Patients reporting for attention are taken privately into the consultation-room and given whatever medical or surgical attention is necessary. Rigid rules are followed in giving each patient a routine physical examination and prescribing for or admitting the patient according to the exigencies of the case. Patients admitted, whether medical, surgical, obstetric, or whatever the condition may be, are in the exclusive charge of the physician in attendance, and he is directly responsible to the patient, on the one hand, for prompt and efficient service, and to the hospital and indirectly to the companies on the other, for the result.

Each physician is responsible also for the entire duties incident to caring for the patient and must attend to those features of treatment which fall outside the nurses' duties. In addition to these things each physician is responsible for whatever laboratory or pathologic work may be required, such as taking and examining throat cultures, blood specimens, feces and urine analysis. By this system we eliminate the necessity for intern and clinical microscopist, thereby saving quite an item in expense.

Members of the Staff.—Just as in all systematized business concerns a chief is essential, so it is with a properly managed hospital. Our chief surgeon, though relegating to each member of the staff his duties and granting that so far as the physician and patient are concerned whatever the physician does, within reasonable limits, is supreme, still he retains the position in act and deed of supreme medical director to whom all affairs of the medical department are entrusted, and he is directly responsible to the companies for the entire affairs of the institution. We therefore have all members of the staff proceeding in pursuance of their duties unmolested, yet responsible to the chief surgeon. This enables us to conduct a rigidly disciplined staff, all working in harmony together.

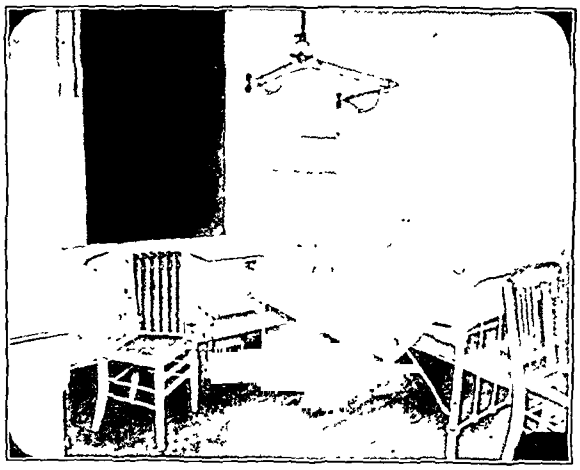

Fig. 4.—Private room.

As it is with the medical staff, so it is with the training-school for nurses. The superintendent of nurses has surveillance over the night superior, the operating-room nurse, and all the student nurses; yet she is herself responsible to the chief surgeon. The plan followed in conducting the training-school deserves no comment other than that a scheduled course of lectures with required collateral study is submitted by the superintendent, and each member of the medical staff, together with the superintendent, lectures regularly on their respective subjects. The term of training is two years. I might further add that our training-school, in addition to offering an opportunity for ambitious girls to take up a profession, also enables us to maintain a full corps of nurses at a minimum expense. Each nurse, in addition to her training, board, lodging and laundry, receives an incidental expense allowance of six and eight dollars per month during the time of service of her junior and senior years, respectively.

Aside from the hospital proper, but under the direction of the chief surgeon, we have stationed at two separate logging camps, at distances of 12 and 25 miles, respectively, a physician whose duty it is to look after the sanitary conditions of the camps, and render medical attention to the employees, and first aid to the injured. In cases of serious accidents he is required to bring in the injured on a special train in order that the necessary attention may be promptly administered.

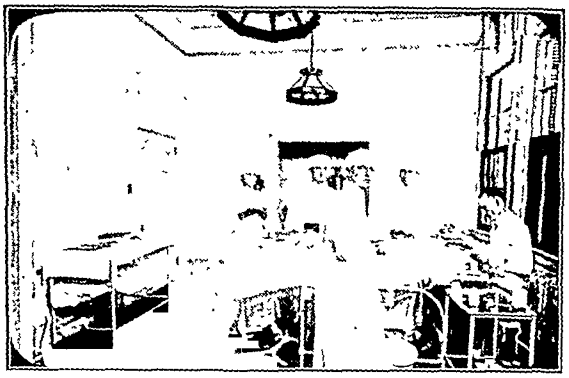

Fig. 5.—Operating room.

DETAILS OF WORK

Having given a general survey of our work, let me now go more into detail with reference to the work we are doing. Our surgical work is taken up according to the following plan: All major work of high grade is taken on Tuesdays, Thursdays and Fridays during the morning. The work is done by the operator assisted by a first and second medical assistant, and the operating-room nurse, the latter handling instruments; in addition there is an anesthetist, usually the house physician, except when he is the operator, in which case the usual second assistant gives the anesthetic. No other regular operating days are observed, all the major surgery of smaller purport and minor cases being done on any afternoon of the week, except Sundays.

We handle all the work regardless of character, except diseases of the eye requiring a specialist and part of our Roentgen-ray work. We have two visiting specialists, one on diseases of the eye, the other on roentgenology, who pay two visits to our hospital each month.

During the year 1912 there were admitted to the hospital 920 patients. Of this number 873 were discharged cured, improved or stationary, 27 were still in the hospital, and 20 died, giving a death-rate of a fraction over 2 per cent. The house visits totaled 13,255, and the office consultations and treatments were 15,138; 1,346 accident cases received attention; 284 surgical operations were performed. Of these 188 were in general surgery and 96 gynecology. Two nurses were graduated from the training-school.

The next point of interest is the hospital maintenance, the source from which comes our revenue. From the first earned wages of each employee each month a certain deduction is made for the hospital fund. For the married man, regardless of size of his family, a deduction of ninety cents is made; for each single man a deduction of seventy cents. This goes into the hospital fund from which all expenses are paid. In return for the deductions the hospital is maintained, medical and surgical services of six physicians supplied, and care given in the hospital for operation or treatment without further charges. Every feature of medical protection is at each employee's command day or night and the hospital is open at all times for any emergency that might arise.

Extra charges are made only for obstetric and venereal work, and then only a nominal fee.

During 1912 our net receipts totaled $30,501.73. Of this the following distribution was made:

Salaries	$18,894.98
Supplies	7,260.37
Other charges	4,346.38

We gained during the year $1.150.69, which, added to what we have gained so far this year, enables us, without inconvenience, to construct and allow for alterations in the main building leading to the establishment of a children's department.

Thus we see the possibilities in the routine practice of a small hospital without vast expenditure or elaborate equipment, and the vast good accruing from such a system.

BRAIN ABSCESS CAUSED BY FUSIFORM BACILLI *

GEORGE F. DICK, M.D.,
AND
LUDWIG A. EMGE
CHICAGO

A report by one of us[1] concerning a number of processes, with which fusiform bacilli were found associated, included three cases of meningitis and one cerebellar abscess. On account of the fact that these organisms were accompanied by streptococci and were, when isolated, non-pathogenic for animals, it was impossible to decide whether or not the fusiform bacilli caused the lesions or were saprophytic invaders of a process caused by the streptococci. An opportunity for additional information was afforded by the following case:

History.—A man aged 40 was admitted to the service of Dr. Dean D. Lewis at the Presbyterian Hospital suffering from severe headache on the left side associated with difficulty in speech. He had had a drainage of a temporosphenoidal abscess three months before that time, with recovery. This had been preceded by a chronic bronchitis. The second abscess was opened and a quantity of foul-smelling pus obtained from which cultures were made. The patient died about a week after the drainage of the abscess. The necropsy report was as follows:

---

* From the Memorial Institute for Infectious Diseases, Chicago.

[1] Dick, George F.: Fusiform Bacilli Associated with Various Pathological Processes, Jour. Infec. Dis., 1913, xii, 191.

Anatomic Diagnosis.—Cerebral abscess, chronic and subacute leptomeningitis, recent and healed operative wounds in the scalp and calvarium, petechial hemorrhages of the heart, stomach and intestine, edema and hypostasis of the lungs, cloudy swelling of the heart and liver, fibrous adhesions between the stomach and pancreas, and between appendix and peritoneum, subacute and chronic follicular enterocolitis, Meckel's diverticulum.

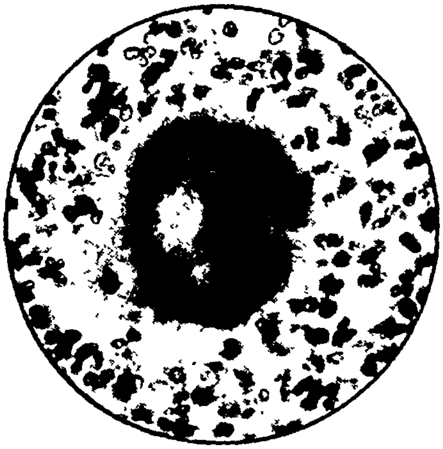

Fig. 1.—Actinomyces-like mass of fusiform bacilli in brain abscess; × 650.

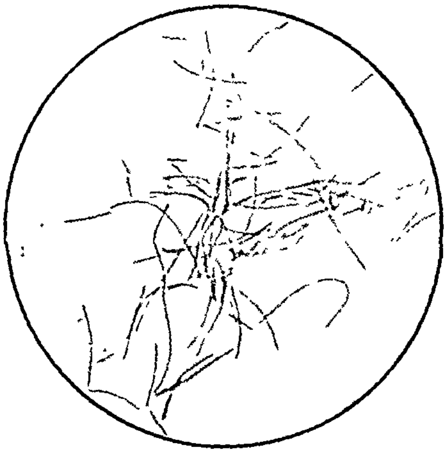

Fig. 2.—Fusiform bacilli from pure culture on blood-agar; × 1,200.

At the base of the nose is a circular opening in the skull 3 cm. wide, the margins of which are smooth. The dura and pericranial tissues are adherent, and the former is markedly thickened at this point. Just above the left ear is a linear incision, coronal in direction, 7 cm. long, the lower 4 cm. of which are gaping. The wound leads into an abscess-cavity located in the left cerebral hemisphere just anterior to the fissure of Sylvius. When the brain is removed, about 125 c.c. of a foul-smelling, dirty gray pus escapes. The ears and accessory sinuses are free from purulent material.

The brain is of normal size, weighing about 1,600 gm. The left hemisphere is somewhat larger than the right one. An abscess varying in width from 0.5 to 2 cm. follows the course of the left sylvian fissure and extends into the temporal, frontal and parietal lobes of the same side. It is filled with a brownish-green mass and ends within the left occipital lobe. The left lateral ventricle is compressed and half as large as the right, which is of normal size. The lesion separates the temporal lobe almost completely from the rest of the cerebrum and breaks into the left lateral ventricle at the beginning of the occipital lobe. The tissues of the affected lobes are infiltrated with brownish and greenish patches which replace the white and gray matter to a considerable extent. The cerebellum was found to be of normal size and without gross lesions.

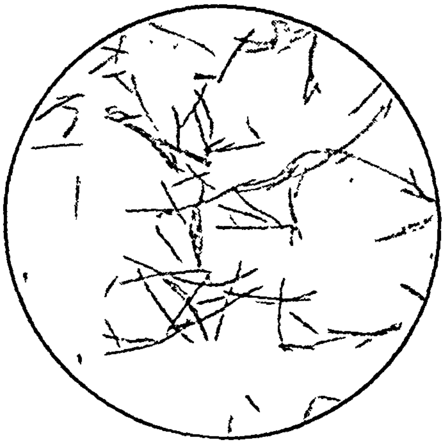

Fig. 3.—Fusiform bacilli from pure culture on blood-agar; × 1,200.

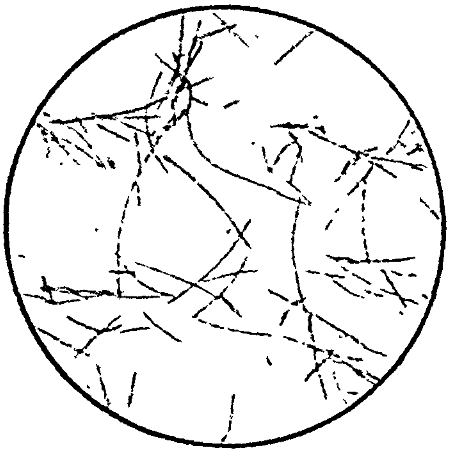

Fig. 4.—Fusiform bacilli from pure culture on blood-agar; × 1,200.

Examinations.—A number of pieces from the sides of the lesion, hardened in formaldehyd solution, were examined microscopically. The most marked changes are found in the middle and posterior third of the medulla and cortex of the left temporal lobe about the fissure of Sylvius. Especially conspicuous are the many large and small areas of necrosis which involve both the white and gray matter. These areas of necrosis are generally sharply demarcated and limited by a zone of fibrous connective tissue. There is also a marked accumulation of polymorphonuclear leukocytes which extends well into the gray matter, which for the greater part is broken down. Larger and smaller fields of recent hemorrhages are present throughout this region.

Between the necrotic areas as well as in the accumulation of polymorphonuclear leukocytes circular masses are seen which simulate in a measure an actinomycotic formation when observed under low magnification. They are invariably surrounded by heavy walls of small round cells and polymorphonuclear leukocytes. Under high magnification these masses are seen to consist of a great number of long slender filaments which radiate about a small ball of central members. Stained with hematoxylin and eosin, an outer small zone which takes the pink stain seems to consist of fine fibrin threads which spread between the surrounding cells. With connective-tissue and fibrin stains (Mallory-Weigert and Weigert-Mallory) it can be made out that these threads are not fibrin but the outer ends of the filamentous organisms. The organisms are Gram-negative when stained by Mallory-Wright and by Weigert's modification of Gram's stain. The groups of organisms vary in number as indicated by the size of the groups, the larger of which are found within the necrosed areas while the smaller groups are limited to the free accumulations of pus.

Anaerobic cultures made from the pus as obtained at the operation yielded a pure culture of fusiform bacilli. The organisms developed in from two to four days on the surface of ascites or blood-agar slants as small drop-like colonies which grew to be about a millimeter in diameter raised well above the surface of the medium. The growth in the water of condensation formed rather discrete colonies in the fluid. In ascites-agar stabs there was no outgrowth into the surrounding medium. The organism did not grow on ordinary mediums without serum or blood. The organisms were Gram-negative, at times distinctly fusiform and rather short, with vacuoles and granules; at times large filaments were formed.

A pure culture from one of the original colonies on blood-agar was injected into the brain of a rabbit. In about twelve hours the animal developed chronic convulsions and died in about thirty-six hours with paralysis of all four extremities.

Course of Disease.—I was inclined to regard the case as one of neurasthenia, exacerbated by auto-intoxication, and prescribed calomel in repeated doses during the day and salts in the morning. The next day the vomiting had ceased and the headache was better, but the speech was worse; the patient was subject to attacks of mental excitement. I advised his removal to hospital. He got up and dressed but I noticed that, although he put his tie-pin in straight, he was quite unable, after several minutes of effort, to adjust the fastener to its point. Romberg's sign was still absent. As he walked to the elevator money fell from his pocket but its loss was unnoticed. He chatted merrily on the way and walked up the hospital steps without effort. Vomiting was absent all that day and headache was slight. Temperature on admission, 97.6; pulse 70; calomel continued, 1/8 grain every two hours.

June 12: Patient had severe headache and sleeplessness during the night, but at 7 a. m. seemed much improved, spoke much more distinctly and grasped ideas better. Temperature 99, pulse 50, respirations 18.

This day a barely detectable weakness of the right arm and a trifling exaggeration of the tendon-jerks and epigastric reflex on the right side was present. The right plantar reflex was still flexor, but the great toe did not go down so briskly or so far as did the great toe on the left side; the second and third toes on the right side went up, but all the left toes went down. The face, upper and lower, moved equally to voluntary and emotional effort. In the absence of any apparent cause for cerebral abscess and the freedom from vomiting, from optic neuritis and from abducent weakness I regarded the case at this time as one of cerebral thrombosis. The presence of gastritis was sufficient to account for the low fever.

June 12: Potassium iodid administration begun and ice-cap applied. Patient complained of some sore throat.

June 13 to June 16: Little change. More or less headache with remissions present. Temperature range, from 98.6 morning, to 99.6 evening. Pulse, 54 to 84, with average of 60. Aphasia decidedly more marked.

June 16, morning: The patient looks and feels better. Right arm is used freely, but when at rest the hand is held in the classic hemiplegic position.

June 17: Marked hebetude. Pain localized on left side of head. Examination of the optic disks at my request by Dr. Frank Miller confirmed a beginning neuritis at the nasal side of each disk.

Operation.—June 17, I turned down an osteoplastic flap, the center of which corresponded to the angular gyrus. The dura bulged slightly and did not pulsate, the cortex was darker than normal and the vessels swollen. A trocar was inserted with a negative result. Exploration deep toward the lenticular nucleus with the little finger disclosed a cavity about the size of a small walnut, which was filled with thick ill-smelling pus. After this was evacuated, another smaller cavity was opened up as the drainage-tube was inserted. The tube was left *in situ* and brought through the center of the osteoplastic flap.

Postoperative History.—June 18, there was pronounced right hemiplegia, the face being only slightly affected.

June 20, the paralysis began to improve, as well as the mental condition and speech, but the drainage was slight from the first.

From June 22 the patient became more comatose and more toxic. June 24, I removed the bone flap and explored the abscess cavities, which were in a satisfactory condition and the meninges were well shut off. On the thirteenth day

The abscess in the optic thalamus presumably caused death. No sign of ear or nose disease was present. The organisms in the pus were declared by Dr. C. W. Bonynge of Los Angeles to be Pfeiffer's bacillus of influenza and *Staphylococcus aureus.*

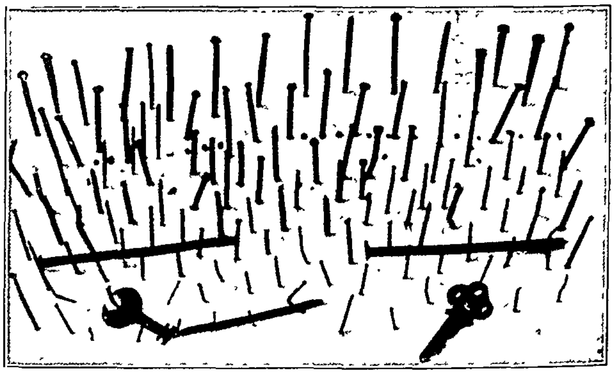
This case to my mind indicates the importance of early exploratory operation in doubtful cases of intracranial disease. I should not have waited for indications of optic neuritis and, although the diagnosis of thrombosis with cerebral softening was justifiable in the absence of any probable cause of abscess, nevertheless a well-executed decompression and inspection of the area indicated by the focal signs can do no great harm in thrombosis, and if in this case it had been performed June 11, instead of June 17, the ultimate result would, I think, have been different.

A similar case is reported by Dr. J. Henderson.[1] The abscess in this case was in exactly the same situation and on the left side but it burst into the ventricle. Dr. Henderson in his report says in conclusion that in such cases with no evidence of the origin of the infection a diagnosis of abscess must always be uncertain.

A CASE OF HARDWARE SWALLOWING

W. O. Wilder, M.D., Pittsfield, Mass.

History.—L. P., aged 41, a carpenter since 16, admitted to the House of Mercy Hospital, Oct. 24, 1912, juggled coins in his mouth and throat, when a youth, for the amusement of his friends. In 1908 he began to swallow nails for money, and later indulged in a diet of knives, cigars, etc., which he would vomit up sometimes and at other times pass by bowel. He said that he was accustomed to swallow 4 feet of 1-inch dog-chain, and women's neck-chains of similar length. These were usually redrawn from the stomach. For the past four or five years the patient has suffered with sharp pains in the abdomen, which were partially relieved by partaking of food. The pains recently had become extremely acute and constant, being localized in the left upper quadrant of the abdomen, and made more severe by any movement of the body.



Foreign bodies removed from the stomach.

Examination.—The bowels were regular and the stools contained no blood. The patient was very much emaciated. The lungs and heart were negative, the abdomen flat and rigid. Pressure demonstrated no tumor but did elicit an extremely tender area in the left upper quadrant. Roentgenoscopy revealed a definite irregular-shaped shadow in the left upper quadrant of the abdomen.

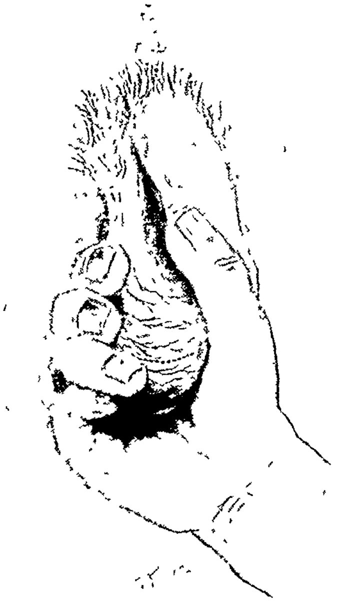
Operation.—An incision was made in the left rectus above of wire were removed. These foreign bodies lay in a pouch-shaped distention of the cardiac end of the stomach and weighed ¾ of a pound in bulk.

Recovery was uneventful.

A TRANSVERSE INCISION FOR OPERATION ON THE SCROTUM

George Morris Dorrance, M.D., Philadelphia
Surgeon to St. Agnes' Hospital

In operations on the scrotum, the longitudinal incision is the one described in all the text-books which I have consulted On examination of the lower half of the scrotum, it will be found that the superficial vessels and nerves run almost transversely. If the incision is placed transversely between the vessels which can easily be seen, injury to many of these structures will be avoided and the incision will be in the line of the folds of the skin. This is well shown in the accompanying illustration. The edges of the incision will approximate themselves and the sutures will make a good even wound. After the removal of the drain, if drainage is required, the edges will fall together. If it is desired to shorten the scrotum, a second transverse incision with excision of the intervening skin and fascia will give the desired results. This method has the advantage of shortening the cremasteric muscle in its entire width, a result not obtained by suturing the longitudinal incision transversely. The longitudinal incision does not produce a neat wound. The dotted line indicates the line of incision.



Transverse incision (indicated by the dotted line) between superficial vessels of scrotum.

2025 Walnut Street.

A Case of Right Inguinal Hernia of Ovary and Tube.—
L. P., student, aged 12, was brought to the office in October,
1913, by her parents because of a right inguinal hernia.
er parents could not remember when the trouble was first
iced, but said that other physicians had told them that
hild was ruptured and prescribed a truss which she had
or some years. Except for the inconvenience of wear-
truss, the hernia troubled her very little. At this
was nothing in the inguinal canal and the hernia
been easily reduced. On December 15 I was
house to see the patient. Two days before,
ring her truss, she coughed and a swelling
right inguinal region, which she was unable
ion a small, oval, tender mass the
d in the right inguinal canal.
distance up and down the
the abdominal cavity. A
ary was made and the
ration the sac was
but no bowel or
n the abdomi-
usual way.
T S. Barr,

A CONGENITAL MALFORMATION OF THE NECK

Charles A. Parker, M.D., Chicago

In May, 1912, the patient, A. F., a girl aged about 11, came to the service of Drs. Blanchard and Parker at the Home for Destitute Crippled Children, for the correction of a peculiar deformity *involving principally* the skin on both sides of the neck. The deformity is well illustrated in Figure 1, and consisted of two symmetrical wing-like folds of skin extending from either mastoid region to the top of the shoulder. These wings had always existed to some extent and changed very little in appearance with muscular contraction. They interfered somewhat with the movements of the head, but it was more on account of the deformity that their removal was sought. The redundant fold of skin was removed by an incision extending from the mastoid to the outer end of the clavicle on either side of the fold leaving an elliptical wound which, when closed, made a more nearly normal-appearing neck (Fig. 2). On account of troublesome anesthesia the two folds were removed at separate operations. The portion removed, besides the skin, contained fibrous tissue in which were included some muscle fibers. No microscopic examination was made. The position of the fold, just behind the ear, was too far forward for the trapezius, and the bottom was too far out on the shoulder for the sternomastoid.

The case is unique as far as our knowledge and experience go and we can offer no plausible explanation of its development. The family history, however, suggests a very definite factor in its origin. The father has locomotor ataxia, an older sister has a congenital dislocation of the hip and five children died during infancy, one being still-born.

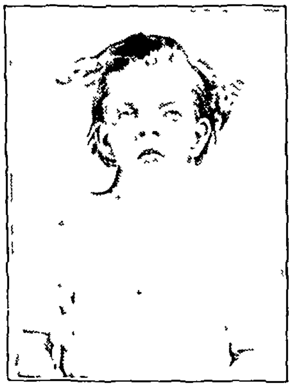


Fig. 1.—Congenital malformation of the neck.

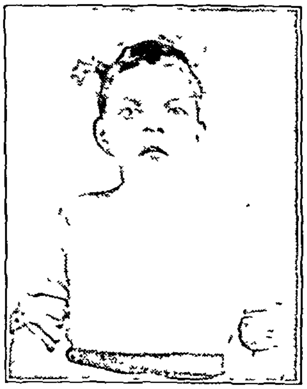

Fig. 2.—Patient in Figure 1 after operation.

The accompanying illustrations show the facial characteristics of this child. Later she developed a dislocation of the patella, resembling the congenital type, which was cured by operation.

7 West Madison Street.

Morbidity Statistics in the United States.—We must not let ourselves be blinded by statistics, for the statistics of disease in the United States are notoriously unreliable. For certain sections no attempt whatever is made to collect them. * * * Until severe penalties are inflicted for failure to report cases of infectious diseases, until failure to do so results in the cancellation of the license to practice medicine, there will be no really reliable statistics. And this will only be brought about when the state health services throughout the land furnish a permanent career for life instead of being, as they are but too often at present, a side-line of politics—medical or otherwise. And these services should furnish a career like the federal civil service, to sanitary engineers and chemists as well as to physicians. The people must learn that their health is too valuable to entrust to temporary health officers or to physicians who devote to the discharge of their duties as health officers only such irregular moments as can be spared from private practice.—Carl L. Alsberg, *Am. Jour. Pub. Health.*

The meningeal fluid was found at necropsy to be rich in polymorphonuclear leukocytes, and fusiform bacilli were found in smears and cultures from the fluid. The lateral ventricles were filled with thin pus from which the organisms were also recovered in pure culture. A slant of this culture was injected into the brain of a second rabbit, and this animal died in much the same way as the first. In this animal a small abscess was found just outside of the right lateral ventricle, with necrosis of the surrounding tissue. The tissue was examined for actinomyces-like bodies similar to these described in the necropsy, but none were found. Two rabbits injected intrameningeally died in about thirty-six hours in convulsions. In these rabbits there was very little exudate on the meninges, but only a diffuse hyperemia. At this point a contamination of the strain which was being passed through rabbits occurred, and experiments were resorted to with subcultures from the original growth, which had been over a month. Injection of a culture of these organisms into the meninges was without result. Later it was found that intrameningeal injections of the growth from a dozen slants were apparently harmless for rabbits. One animal received three injections of large quantities of the organisms with no harmful results. The cultures had lost their pathogenicity. It is not improbable that the readiness with which pathogenicity is lost in these organisms explains the negative results of attempts to produce lesions in animals, as the isolation in pus culture of fusiform bacilli is often time-consuming.

The finding of the actinomyces-like bodies in an abscess from which pure cultures of fusiform bacilli were obtained has direct bearing on the identity of the so-called ray fungi commonly found in tonsils. These bodies have been commonly mistaken for actinomycelial granules. Davis[2] believes these granules to be composed of streptococci, spirilla and organisms of the fusiform group.

The filaments composing the bodies found in the brain in this case resemble closely the organisms cultivated from the pus containing them.

HEREDITY IN BONE LESIONS

WITH THE REPORT OF AN UNUSUAL FAMILY HISTORY *

JOSEPH RANSOHOFF, M.D., F.R.C.S. (Eng.)
CINCINNATI

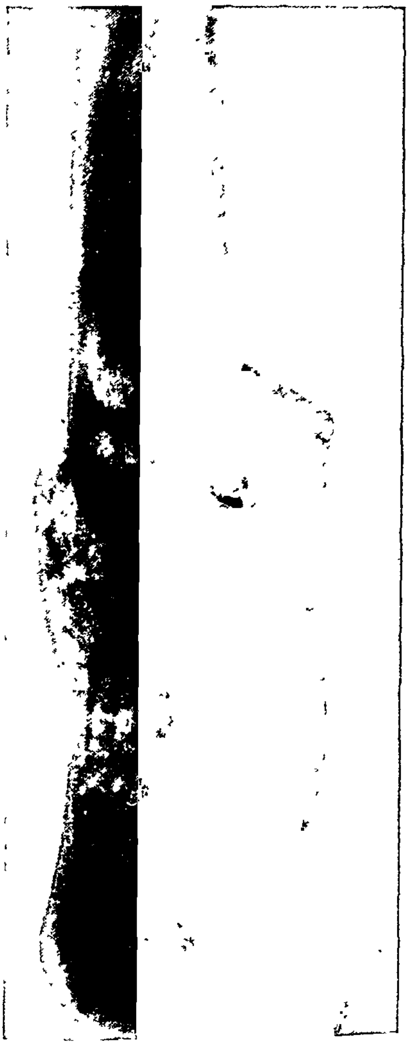
Because it has been my unusual privilege to come into personal contact with morbid heredity through three generations of one family, I take the opportunity of presenting, in brief, the histories of four patients of three separate generations.

Case 1.—Mrs. M. X., aged 68, was born in England, there was no obtainable history of hereditary disease. Her husband who was short of stature, had no hereditary pathologic history. He died of senility at 79. One brother died of acute nephritis at 47, and one sister of diabetes at the age of 70. The patient had been well until four or five months before she came under my observation, in July of 1891. During these months she suffered severely from pains in the lower third of the thigh. They were supposed to be rheumatic. In attempting one morning to get out of bed she sustained a spontaneous fracture. At the site of this a tumor rapidly formed, for which an amputation was made. The patient died Sept. 18, 1891, of pulmonary metastasis.

The specimen showed a mixed sarcoma of the femur with spontaneous fracture. This was before the days of roentgenography. Fortunately the specimen was preserved, and has been roentgenographed (as shown in the accompanying illustration). The disease was limited to about 3 inches of the lower third of the femur and stopped short of the condyles. The compact tissue and the medulla for 2 inches above the main tumor mass show alternating areas of bone rarefaction and hyperplasia. On the surface the growth has completely surrounded the femoral shaft in the form of a ring 2 inches wide encircling the line of fracture. With the invasion of the soft parts the myeloma evidently assumed the malignancy of the sarcoma group in general.

Mrs. X. had two daughters and two sons. One of the daughters has remained single and well, except for a cystic disease of the breast. The second daughter is married and has three children, all of them well. The two sons are Patients 2 and 3.

Case 2.—S. X., aged 48, younger son of Patient 1, in 1890 contracted syphilis which was apparently cured by the treatment then in vogue. In January, 1899, he first complained of pains in the right hip and became lame. Being told that the condition was probably luetic, he submitted to a long course of treatment at Hot Springs, without effect. Trips to various health resorts failed to bring relief. When I first saw the patient he presented the following condition: In face and stature, he resembled his mother. The right thigh is in moderate abduction and slightly flexed. Between the trochanter and the iliac crest is seen a distinct fulness which extends forward to the anterior surface of the thigh. The mass was evidently deep-seated in its origin. A roentgenogram, which unfortunately has been lost, showed an osteosarcoma of the femoral neck which had invaded the trochanter, completely destroying it. Although an exarticulation at the hip was advised, it was not urged. The tumor grew very rapidly, invaded the skin, and death from recurrent hemorrhages ensued in March of 1900, fourteen months after the onset of symptoms.



Mixed central sarcoma of femur with spontaneous fracture. Roentgenogram taken from specimen twenty-two years after amputation.

A necropsy was not permitted, nor could a part of the tumor be obtained. Although this case was probably from the beginning, on account of its malignancy, a sarcoma of periosteal origin, the possibility of its having been primarily a myeloma cannot be definitely excluded.

Case 3.—J. X., older son of Patient 1, showed more than ordinary family resemblance to his mother and brother. There is no history of syphilis. Patient was in excellent health until he had passed his fiftieth year. He then developed a typical osteitis deformans, beginning with the bowing of both tibiae.

---

[2] Davis: Personal communication.

* Read before the Southern Surgical Association, Dec. 17, 1913.

The femurs followed next, and then the necks of both femurs. In the course of three or four years the spine became progressively involved so that in walking the upper part of the trunk was almost parallel with the floor. Locomotion became exceedingly difficult and was made possible only by the use of two heavy canes. The case was one of osteitis deformans and ended fatally at 64. The immediate cause of death was nephritis.

Case 4.—F. X., born in 1888, daughter of Patient 3, came under my observation when she was a year old. The patient who is now living and 25 years old, resembles the mother very closely in stature, color and facial characteristics. She has one younger brother and one sister. Both resemble the father. They seem normal in every way.

When the patient was 6 months old it was found that she could bear no weight on the left foot. An examination revealed a break in the lower end of the tibia and a slight shortening of the leg and foot. There was no other deformity. There had been no history of an injury. The manipulations were not in the least painful. All efforts to obtain union in the fracture by the ordinary means failed, and the limb could not be made to bear weight. When the child was 4 years old the affected leg was 2 inches short. The foot was shorter than its fellow and poor in its circulation. An operation was now performed with a view in some manner of bringing the fragments into contact. The exploration revealed an intact fibula. The upper fragment of the tibia was bulbous and eburnated. The lower fragment was triangular, very atrophic and terminated above in an almost dagger-like point. At the operation the upper fragments were vivified and the lower firmly fixed in the medulla. This of course, was before the technic of bone-grafting was far developed. The result was unsatisfactory. The roentgenogram taken when the patient was 11 years old showed that the operation had not improved the condition. It was much as it had been before the operation.

Prostheses of various kinds had to be restorted to. Without them, locomotion was impossible. The roentgenogram taken two years later showed that the fibula had also broken. The leg was a little over 3 inches shorter than the other. Trophic changes in the foot, such as painful though superficial ulcerations, made life so intolerable that when the patient was in her sixteenth year an amputation was made below the knee as a matter of election.

The pathologic nature of this case is a puzzle difficult to solve. Was it an unrecognized case of intra-uterine or intrapartum fracture? Was it a fracture at all, or was it from the beginning an imperfect osteogenesis? I am inclined to believe that it was the latter, in view of the family tendency to bone lesions, and because the ordinary concomitance of intra-uterine fracture, such as bowing of the tibia, the amniotic scar over the fracture and other deformities of the leg and foot were absent. Furthermore, the theory of imperfect bone genesis fits in with the remarkable tendency to bone lesions in the family.

In 20 per cent. of the cases of osteitis deformans a hereditary tendency has been found to exist. In many of them, death results from sarcoma developing in previously affected bones. Indeed, Paget's first patient died of sarcoma of the ulna. There are ranking pathologists to-day who believe that the medullary bone sarcoma is not a sarcoma at all, but only a variant of the fibrous osteitis, which so often ends in bone deformity.

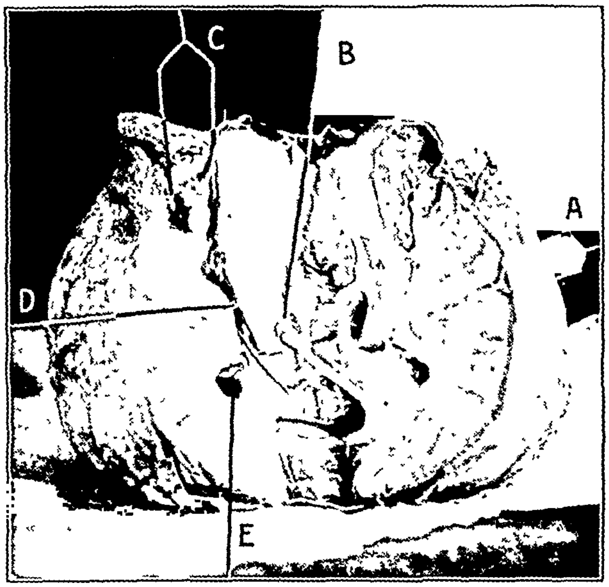
Therefore, in three of my cases the similarity, if not identity of the bone lesions, must be conceded. In the fourth and last case the morphologic kinship, though undoubted, is not so clear.

I am safe in saying that in all these cases bone tissue was by heredity a *locus minoris resistentiae*, a phrase little used during the last decades, in which the bacteriologists pushed aside our theories of the causes of disease. But for many things we are forced to fall back on heredity. The *locus minoris* of our fathers is still the weak spot, only the modern experimental biologist calls it the "recessive." The future alone can tell how far-reaching was the study of that humble Augustinian friar who, in the little walled garden of his cloister at Brunn, looked on the humble garden pea with a higher thought than that if there were enough of them, they made a good meal on Friday.

A CASE OF BRAIN ABSCESS

Cecil E. Reynolds, M.R.C.S., L.R.C.P. (London);
D.P.H. (Cambridge); Los Angeles

Patient.—F. D. T., a publisher, arrived in Los Angeles June 10, 1913. He was ill during the night of June 9, with some headache and nausea, but as for years past he had been subject to attacks of "nervous prostration" which were accompanied by headache and vomiting, he did not regard the attack as particularly serious. June 10, during a business interview, he could not express himself as lucidly as was necessary; in consequence he became excited and was removed to his hotel, where I saw him about 4 p. m.



Coronal section of brain 1 inch behind the midpoint; *a*, anterior portion of brain; *b*, metastatic abscess in left thalamus; *c*, primary abscesses; *d*, velum separating left ventricle from abscess; *e*, right lateral ventricle.

I found a healthy, intelligent-looking man, aged 46, of spare build and showing no signs of alcoholism or other degenerative stigmata. He was sitting up in bed, vomiting a watery bile at intervals; he complained of some generalized headache and an inability to find the right word. He had often had these attacks, but never such marked amnesia. He had recently been under great worry and mental strain. He had taken no alcohol and had never had syphilis.

Examination.—Heart and lungs normal, tongue heavily coated and bowels constipated. Temperature 99 F., pulse 85. Cranial nerves normal; no ptosis, strabismus or nystagmus. Power and sensation equal and unaltered; no ataxy. Romberg sign absent. Superficial reflexes equal and normal; deep reflexes equal and moderately exaggerated. Optic disks normal; no contraction of the fields of vision. Patient could read fairly well, though with some hesitancy; when writing to dictation it was well executed, but he was easily fatigued. No disease of scalp, ears or nose. In conversation he showed marked forgetfulness of names.

Course of Disease.—I was inclined to regard the case as one of neurasthenia, exacerbated by auto-intoxication, and prescribed calomel in repeated doses during the day and salts in the morning. The next day the vomiting had ceased and the headache was better, but the speech was worse; the patient was subject to attacks of mental excitement. I advised his removal to hospital. He got up and dressed but I noticed that, although he put his tie-pin in straight, he was quite unable, after several minutes of effort, to adjust the fastener to its point. Romberg's sign was still absent. As he walked to the elevator money fell from his pocket but its loss was unnoticed. He chatted merrily on the way and walked up the hospital steps without effort. Vomiting was absent all that day and headache was slight. Temperature on admission, 97.6; pulse 70; calomel continued, ⅛ grain every two hours.

June 12: Patient had severe headache and sleeplessness during the night, but at 7 a. m. seemed much improved, spoke much more distinctly and grasped ideas better. Temperature 99, pulse 50, respirations 18.

This day a barely detectable weakness of the right arm and a trifling exaggeration of the tendon-jerks and epigastric reflex on the right side was present. The right plantar reflex was still flexor, but the great toe did not go down so briskly or so far as did the great toe on the left side; the second and third toes on the right side went up, but all the left toes went down. The face, upper and lower, moved equally to voluntary and emotional effort. In the absence of any apparent cause for cerebral abscess and the freedom from vomiting, from optic neuritis and from abducent weakness I regarded the case at this time as one of cerebral thrombosis. The presence of gastritis was sufficient to account for the low fever.

June 12: Potassium iodid administration begun and ice-cap applied. Patient complained of some sore throat.

June 13 to June 16: Little change. More or less headache with remissions present. Temperature range, from 98.6 morning, to 99.6 evening. Pulse, 54 to 84, with average of 60. Aphasia decidedly more marked.

June 16, morning: The patient looks and feels better. Right arm is used freely, but when at rest the hand is held in the classic hemiplegic position.

June 17: Marked hebetude. Pain localized on left side of head. Examination of the optic disks at my request by Dr. Frank Miller confirmed a beginning neuritis at the nasal side of each disk.

Operation.—June 17, I turned down an osteoplastic flap, the center of which corresponded to the angular gyrus. The dura bulged slightly and did not pulsate, the cortex was darker than normal and the vessels swollen. A trocar was inserted with a negative result. Exploration deep toward the lenticular nucleus with the little finger disclosed a cavity about the size of a small walnut, which was filled with thick ill-smelling pus. After this was evacuated, another smaller cavity was opened up as the drainage-tube was inserted. The tube was left *in situ* and brought through the center of the osteoplastic flap.

Postoperative History.—June 18, there was pronounced right hemiplegia, the face being only slightly affected.

June 20, the paralysis began to improve, as well as the mental condition and speech, but the drainage was slight from the first.

From June 22 the patient became more comatose and more toxic. June 24, I removed the bone flap and explored the abscess cavities, which were in a satisfactory condition and the meninges were well shut off. On the thirteenth day following the operation, however, the patient gradually sank and died.

Post-Mortem Findings: No meningitis existed beyond the field of operation. There were two abscess cavities side by side in the white matter of the angular and intraparietal lobes, each rather larger than half a walnut. The anterior one led by a narrow channel to a recent abscess the size of a hazelnut in the left optic thalamus. The other abscess cavity was separated from the left lateral ventricle by a narrow velum only. The abscess in the optic thalamus presumably caused death. No sign of ear or nose disease was present. The organisms in the pus were declared by Dr. C. W. Bonynge of Los Angeles to be Pfeiffer's bacillus of influenza and *Staphylococcus aureus.*

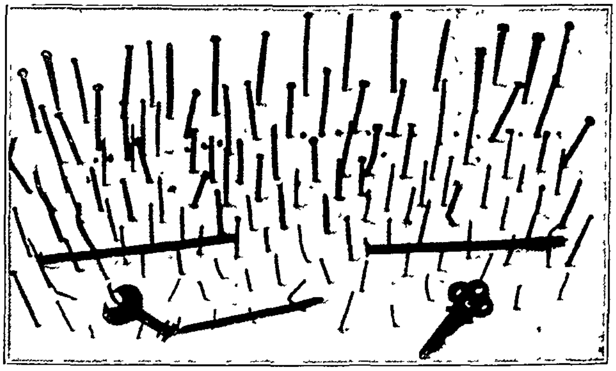
This case to my mind indicates the importance of early exploratory operation in doubtful cases of intracranial disease. I should not have waited for indications of optic neuritis and, although the diagnosis of thrombosis with cerebral softening was justifiable in the absence of any probable cause of abscess, nevertheless a well-executed decompression and inspection of the area indicated by the focal signs can do no great harm in thrombosis, and if in this case it had been performed June 11, instead of June 17, the ultimate result would, I think, have been different.

A similar case is reported by Dr. J. Henderson.[1] The abscess in this case was in exactly the same situation and on the left side but it burst into the ventricle. Dr. Henderson in his report says in conclusion that in such cases with no evidence of the origin of the infection a diagnosis of abscess must always be uncertain.

A CASE OF HARDWARE SWALLOWING

W. O. Wilder, M.D., Pittsfield, Mass.

History.—L. P., aged 41, a carpenter since 16, admitted to the House of Mercy Hospital, Oct. 24, 1912, juggled coins in his mouth and throat, when a youth, for the amusement of his friends. In 1908 he began to swallow nails for money, and later indulged in a diet of knives, cigars, etc., which he would vomit up sometimes and at other times pass by bowel. He said that he was accustomed to swallow 4 feet of 1-inch dog-chain, and women's neck-chains of similar length. These were usually redrawn from the stomach. For the past four or five years the patient has suffered with sharp pains in the abdomen, which were partially relieved by partaking of food. The pains recently had become extremely acute and constant, being localized in the left upper quadrant of the abdomen, and made more severe by any movement of the body.



Foreign bodies removed from the stomach.

Examination.—The bowels were regular and the stools contained no blood. The patient was very much emaciated. The lungs and heart were negative, the abdomen flat and rigid. Pressure demonstrated no tumor but did elicit an extremely tender area in the left upper quadrant. Roentgenoscopy revealed a definite irregular-shaped shadow in the left upper quadrant of the abdomen.

Operation.—An incision was made in the left rectus above the umbilicus. An adhesion of stomach to the abdominal wall was freed and a small perforation of stomach was found through which protruded the point of a nail. After the field of operation had been thoroughly walled off with gauze, the perforation was so enlarged as to admit the hand, and two keys, two twelvepenny nails and 130 other nails and pieces of wire were removed. These foreign bodies lay in a pouch-shaped distention of the cardiac end of the stomach and weighed ¾ of a pound in bulk.

---

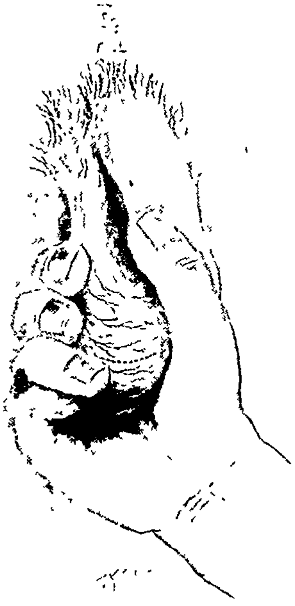
Recovery was uneventful.

A TRANSVERSE INCISION FOR OPERATION ON THE SCROTUM

George Morris Dorrance, M.D., Philadelphia
Surgeon to St. Agnes' Hospital

In operations on the scrotum, the longitudinal incision is the one described in all the text-books which I have consulted On examination of the lower half of the scrotum, it will be found that the superficial vessels and nerves run almost transversely. If the incision is placed transversely between the vessels which can easily be seen, injury to many of these structures will be avoided and the incision will be in the line of the folds of the skin. This is well shown in the accompanying illustration. The edges of the incision will approximate themselves and the sutures will make a good even wound. After the removal of the drain, if drainage is required, the edges will fall together. If it is desired to shorten the scrotum, a second transverse incision with excision of the intervening skin and fascia will give the desired results. This method has the advantage of shortening the cremasteric muscle in its entire width, a result not obtained by suturing the longitudinal incision transversely. The longitudinal incision does not produce a neat wound. The dotted line indicates the line of incision.



Transverse incision (indicated by the dotted line) between superficial vessels of scrotum.

2025 Walnut Street.

A Case of Right Inguinal Hernia of Ovary and Tube.—L. P., student, aged 12, was brought to the office in October, 1913, by her parents because of a right inguinal hernia. Her parents could not remember when the trouble was first noticed, but said that other physicians had told them that the child was ruptured and prescribed a truss which she had worn for some years. Except for the inconvenience of wearing the truss, the hernia troubled her very little. At this time there was nothing in the inguinal canal and the hernia had always been easily reduced. On December 15 I was called to the house to see the patient. Two days before, while not wearing her truss, she coughed and a swelling appeared in the right inguinal region, which she was unable to reduce. On examination a small, oval, tender mass the size of an almond was found in the right inguinal canal. This could be moved a certain distance up and down the canal but could not be replaced in the abdominal cavity. A probable diagnosis of hernia of the ovary was made and the child sent to the hospital. At the operation the sac was found to contain the right ovary and tube but no bowel or omentum. The ovary and tube were replaced in the abdominal cavity and the wound closed in layers in the usual way. The subsequent history is of no interest.—Albert S. Barr, M.D., Greenville, Mich.

A CONGENITAL MALFORMATION OF THE NECK

Charles A. Parker, M.D., Chicago

In May, 1912, the patient, A. F., a girl aged about 11, came to the service of Drs. Blanchard and Parker at the Home for Destitute Crippled Children, for the correction of a peculiar deformity involving principally the skin on both sides of the neck. The deformity is well illustrated in Figure 1, and consisted of two symmetrical wing-like folds of skin extending from either mastoid region to the top of the shoulder. These wings had always existed to some extent and changed very little in appearance with muscular contraction. They interfered somewhat with the movements of the head, but it was more on account of the deformity that their removal was sought. The redundant fold of skin was removed by an incision extending from the mastoid to the outer end of the clavicle on either side of the fold leaving an elliptical wound which, when closed, made a more nearly normal-appearing neck (Fig. 2). On account of troublesome anesthesia the two folds were removed at separate operations. The portion removed, besides the skin, contained fibrous tissue in which were included some muscle fibers. No microscopic examination was made. The position of the fold, just behind the ear, was too far forward for the trapezius, and the bottom was too far out on the shoulder for the sternomastoid.

The case is unique as far as our knowledge and experience go and we can offer no plausible explanation of its development. The family history, however, suggests a very definite factor in its origin. The father has locomotor ataxia, an older sister has a congenital dislocation of the hip and five children died during infancy, one being still-born.

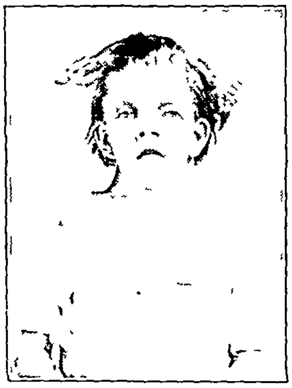


Fig. 1.—Congenital malformation of the neck.

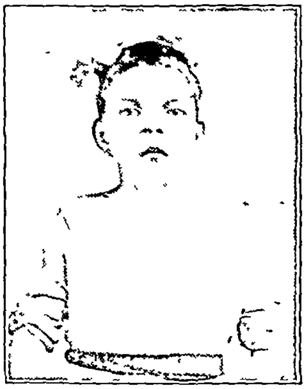

Fig. 2.—Patient in Figure 1 after operation.

The accompanying *illustrations* show the facial characteristics of this child. Later she developed a dislocation of the patella, resembling the congenital type, which was cured by operation.

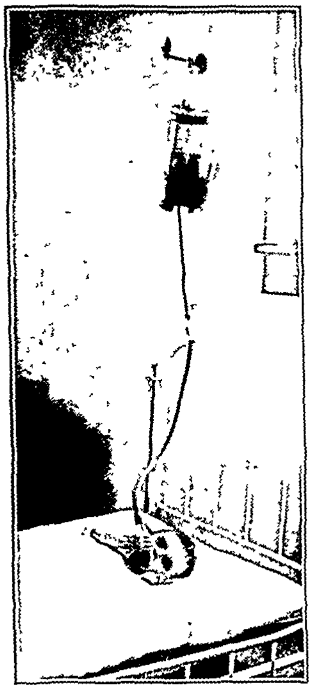
Morbidity Statistics in the United States.—We must not let ourselves be blinded by statistics, for the statistics of disease in the United States are notoriously unreliable. For certain sections no attempt whatever is made to collect them. * * * Until severe penalties are inflicted for failure to report cases of infectious diseases, until failure to do so results in the cancellation of the license to practice medicine, there will be no really reliable statistics. And this will only be brought about when the state health services throughout the land furnish a permanent career for life instead of being, as they are but too often at present, a side-line of politics—medical or otherwise. And these services should furnish a career like the federal civil service, to sanitary engineers and chemists as well as to physicians. The people must learn that their health is too valuable to entrust to temporary health officers or to physicians who devote to the discharge of their duties as health officers only such irregular moments as can be spared from private practice.—Carl L. Alsberg, *Am. Jour. Pub. Health.*

New Instruments and Suggestions

THE MOUTH-DRIP: A METHOD OF ADMINISTERING FLUID TO INFANTS IN GASTRO-ENTERITIS (ALIMENTARY INTOXICATION)

ALFRED F. HESS, M.D., NEW YORK

In the acute gastro-intestinal disturbances of infants, an excessive loss of fluid constitutes one of the greatest dangers to which the infants are subjected. Metabolism studies have shown this, and it is evident to even the casual observer. The dry skin, the parched mouth, the sunken eyes, the depressed fontanel, are striking evidences of a marked depletion of the body fluids. This condition is seen in its greatest intensity when the watery stools are marked and frequent and vomiting is repeated; but it is encountered also in those cases which are mainly toxic in character and which preeminently deserve Finkelstein's appellation of alimentary intoxication. In such cases there may be little or no vomiting, the diarrhea may have almost ceased, and yet the extreme prostration, the apathy or semistupor afford unmistakable evidence that the situation is critical. At this time, we know, food must be at first entirely withheld, and then given only in minimal amounts. If it is given even in moderate amount and in correct formula it acts as a food-poison, increasing the stupor and leading rapidly to death. At this period of the disease the most essential therapeutic measure is to supply the infant, in one way or another, with a large amount of fluid. Almost all textbooks emphasize this point; urging that under such conditions small quantities of water be given frequently. This can be accomplished in various ways. The fluid may be proffered every fifteen minutes or half-hour by mouth, it may be introduced by means of hypodermoclysis, or, finally, it may be instilled into the rectum.



Mouth-drip Infant sucking on nipple. The glass dropper and regulating stop-cock may be seen just above upper rail of bed. Care should be taken that the tube does not drag, and, by its own weight, tend to be pulled away from the mouth of the infant. In order to avoid this, it can be suspended vertically (as shown in the illustration) or, still better, it can be so arranged that the part near the nipple rests horizontally on the bed. To obviate, furthermore, a tendency of the nipple to be pulled away, it will be noticed that the comparatively heavy glass dropper is placed at a considerable distance from the nipple. Another detail, perhaps worthy of mention, is that before the drip is started the fluid is allowed to fill the entire tube; after it is filled, the regulating pinch-cock is applied so that the fluid falls drop by drop.

In the course of the past year I have made use of an expedient which seems to me serviceable in this connection, and therefore of sufficient importance to bring to the attention of those who have to treat this type of disease. In brief, it consists of applying what is popularly known as the Murphy drip-method (by means of which water is given drop by drop by rectum) to the giving of water by mouth—or, in other words, a "mouth-drip." This method has the advantage that fluid entering the upper intestinal tract is absorbed more completely than that which is given subcutaneously or by rectum. Furthermore, in acute enteritis the irritability of the bowel is so marked that the rubber nozzle is not well retained and, indeed, intensifies the diarrhea.

The apparatus (as shown in the accompanying illustration) is the same as the rectal drip except that, instead of a hard rubber nozzle, an ordinary rubber nipple is attached to the end of the tubing by means of a glass connecting-piece. The baby is encouraged to suck on this nipple for the greater part of the day and in this way obtains a large amount of water, hypotonic salt solution, Ringer's solution or other fluid.[1] I have had the drip so regulated by means of a pinch-cock that from about 25 to 30 drops per minute fall from the glass-dropper into the tube. In every case of enteritis in the hospital an apparatus of this kind has been suspended next to the bed. By this means these infants have received about a quart of water in the course of the twenty-four hours, the amount of fluid naturally depending on their thirst and on the degree of the poisoning. Often in the early stages, when the tongue is dry and parched, they will suck almost continuously on the nipple and cry when it is removed, whereas later, when entering on convalescence, they will no longer take to it so greedily. The nipple at times falls from the mouth, the infant releasing its hold. In order that the bed-covering shall not be made wet in this way a little saucer or plate is placed next to the baby's head. The nurse, therefore, has to replace the nipple from time to time. This does not entail near the amount of labor or individual attention which would be required were the infant to receive the same amount of fluid by bottle or spoon in the course of twenty-four hours. To accomplish this end, the nurse would have to offer the water or other fluid many times in the course of an hour. In my experience, this is practically impossible in an infants' ward. If there is one nurse to one or two babies, she can devote her attention to supplying the infants with sufficient fluid; but in the ordinary infants' wards, so many other duties fall on the nurses that the infants, unable as they are to give utterance to their wants, lie often for hours in urgent need of fluid. It must, I think, be a common experience that when a spoonful of water is offered to an infant suffering from alimentary intoxication, it is gulped down greedily by the thirsty baby as if it had not received any water for hours. So great is the absorptive power of the mucous membranes in these cases that the tongue becomes parched in a very few minutes after water has been administered.

It may be urged that by keeping a nipple in the baby's mouth we are encouraging the formation of a bad habit. This criticism, however, can hardly be entertained in a consideration of the treatment of a disease involving a mortality so high as that of gastro-enteritis of infants. In the light of recent studies in metabolism, demonstrating the marked difference between the expenditure of energy in infants that are quiet and in those that are restless, it is, indeed, questionable whether this procedure does not possess additional advantages through its quieting effect and through the conservation of calories which it in this way accomplishes.

This "mouth-drip" is brought forward not with the idea of presenting a novel device, but merely as a simple method of facilitating the introduction of large quantities of fluid, more especially in alimentary intoxication, but also in other toxic conditions of infants and in pyelitis, in which large quantities of fluids are indicated. It is particularly applicable to the hospital ward, where the infants cannot have the individual attention of a nurse.

A SIMPLE CYSTOSCOPE HOLDER

LOUIS FRIEDMAN, M.D., NEW YORK

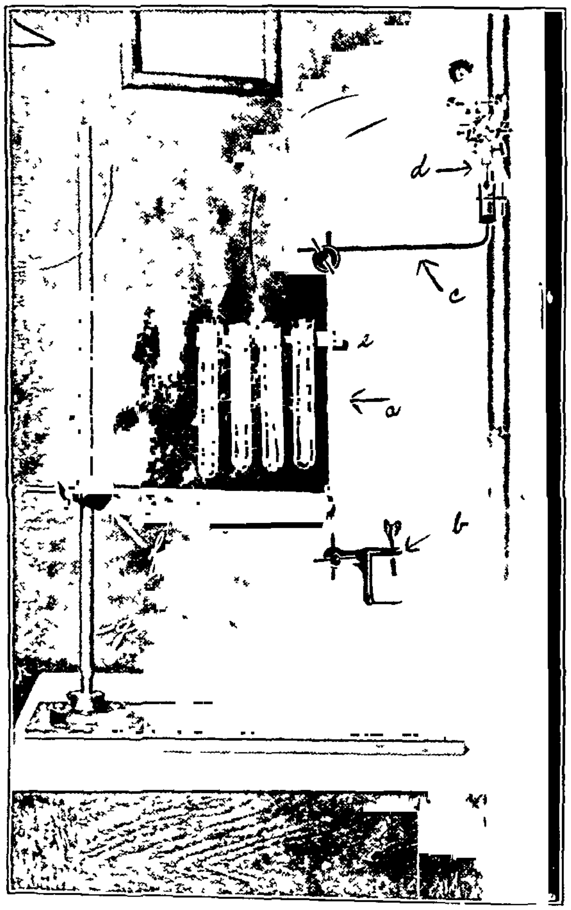
Cystoscope holders are made either in the form of a floor-stand or to be attached to the examining-table. They are usually either too heavy or too bulky for supporting a light instrument like a cystoscope, while some are complicated and clumsy.

---

[1] The addition of a small amount of saccharin to the water frequently results in the babies' taking still larger quantities.

I have constructed a holder which is easy to manage, simple in construction, light and strong and will hold any kind and size of cystoscope in any position desired. It is attached to the table or to the leg-holder rod. During cystoscopy it can be swung out of the way when not wanted and is not in the way when in use because of its small size and compactness. It holds the cystoscope in a steady position while urine is being collected from either kidney; it is very useful when one has to work without assistance and particularly convenient and practical for demonstration purposes as the cystoscope stays exactly where placed, so that the field in the bladder under observation can be studied at leisure.

The perpendicular bar (*a*) is 12 inches long, held by the clamp (*b*) which is attached to the side of the table. The horizontal bar (*c*) is 8 inches long, can be swung to any angle and holds the cystoscope by a clamp (*d*), this being a ball-and-socket joint, giving a wide range of motion. To the bar (*a*) is attached a holder (*e*) for centrifuge glass or test-tubes, into which urine is to be collected. It is more desirable and much simpler if Clamp *b* can be used for attaching the cystoscope holder to the table; but some tables are so constructed that this cannot be done. Then Clamp *f* must be used instead, which is attached to the leg-holder rod (represented in the illustration by *g*), through which clamp runs a horizontal bar supporting the rest of the apparatus. It weighs about 9 ounces.



Cystoscope holder.

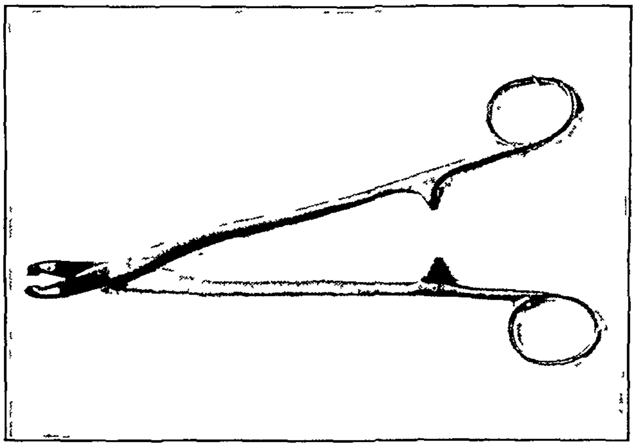
262 West One Hundred Thirteenth Street.

Public Education.—Restrictions of personal liberty, in order to be enforced and to be of any value, must be understood and supported by the public. But the people will only submit to such restriction of their individual liberty as they are convinced is necessary for their own good.

UTERINE SPECIMEN FORCEPS

W. C. Gayler, M.D., St. Louis

This is an instrument to facilitate the removal of small particles from the cervix uteri for microscopic examination, in order to determine the presence or absence of malignant changes. It removes a piece of the cervical mucosa and submucous tissue, with a cut as clean as a razor cut. The specimen can be taken from the suspected spot with great precision, and more than one specimen can be taken from the patient if desired.



Uterine specimen forceps.

It is not necessary to dilate the cervix, or to use a volsellum forceps or an anesthetic. These specimens can be taken with great frequency during ordinary office examinations.

To the man who fears that the partial removal of a malignant growth might stimulate to active growth the part that remains, I suggest a procedure as follows: Prepare the patient for operation, remove one or more particles for examination, and then after the pathologist has given his report, begin the anesthetic.

The handle is 7 inches long. The part beyond the joint is 1¼ inches long. The disks are perfectly round, not oval, and are ¼ inch in diameter.

3905 Olive Street.

A NEW MOTOR-MEAL AND LAVAGE TUBE*

Frank Smithies, M.D., Chicago

Stomach-tubes, as ordinarily made, seem to have the following faults: (1) the inferior rubber in their construction, which prevents sterilization by boiling (the only efficient method); (2) small lumina, which frequently render unsatisfactory the aspiration or expression of motor-meals or poorly chymified test-breakfasts; (3) improperly placed, too few or too small fenestra at their distal ends; (4) the incorporation into the tubes of "aspirating bulbs" of questionable service, which are difficult to keep clean. In an effort to remedy some of these defects, we have had constructed tubes of the type to be described. They have given greater satisfaction than any other form in the last fifteen hundred cases in the Mayo Clinic in which the test-meal examination was made.

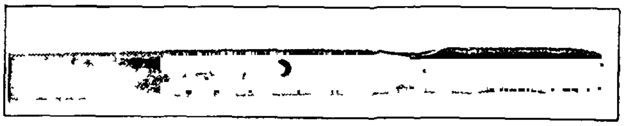


Fig. 1.—Distal end of tube, showing arrangement of fenestra.

---

* From the Mayo Clinic.

The tube is constructed[1] of the best quality of red rubber. The wall is 2 mm. thick and the lumen has a diameter of 9 mm. The tube is made in two sections, distal and proximal, connected by a thin, but strong, aluminum midpiece.

1. The distal segment of the tube is 90 cm. long. It has a distal opening of 1 cm. diameter. Beginning 1 cm. from this tip is a lateral fenestrum (*Fig. 1*) of ellipsoid form, 2 cm. long and 1 cm. wide. On the opposite lateral surface to this is a second similar lateral fenestrum, which begins 3 cm. from the tip of the tube. The fenestrum is placed at this point, not only to permit free siphonage of gastric contents, but also to facilitate the introduction of the tube. Its location, 3 cm. from the tip of the tube, is the average distance in different individuals from the pharyngeal bend of the tongue to the introitus esophagi. When the tip of the tube enters the pharynx, with the second lateral fenestrum toward the tongue, the subject's swallowing motions promptly bend the tube at this fenestrum and the tip glides readily into the esophagus. Using a tube with a distal end of this type, we have not entered the larynx more than a dozen times in our last five thousand cases. Eight centimeters from the tip of the tube are placed three round fenestra, of a diameter of 2 mm. They pierce the tube at the same level. This distal segment of the tube, beginning 10 cm. from its tip, is marked off by encircling black lines (Fig. 2), every 5 cm. for a distance of 55 cm. from the distal end. These markings permit of fairly accurate location of obstructions in the esophagus. The tube, in such instances, acts as a hollow sound through which the contents of esophageal sacculations and the like may be readily secured.

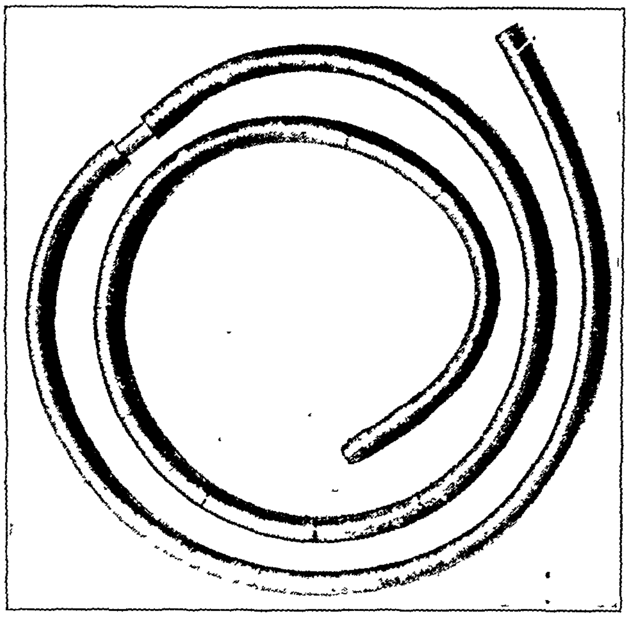

Fig. 2.—Full view of tube, showing segments, markings and fenestra on distal segment and aluminum midpiece (segments separated to show this).

2. The connecting aluminum midpiece is 5 cm. long, with a wall 1 mm. thick and a lumen of 1 cm. diameter. It is slightly roughened and fits snugly into the rubber parts. It is non-rusting.

3. The proximal end of the tube is 60 cm. long. It may be replaced, when necessary, by an aspiration bulb which fits onto the metal midpiece.

The advantages of the type of tube described appear to be:

1. These tubes are durable; they may be boiled for months and still retain their form.

2. The lumen is large enough to permit free expression or aspiration of retention contents after the administration of a motor test-meal.

3. The distal fenestra are so placed as to permit the easy passage of the tube and the rapid siphonage or aspiration of gastric contents. Free lavage is readily carried on, either for the purpose of determining retention (as in hour-glass stomach) or for therapeutic effect.

4. The tube acts as a safe and convenient esophageal sound.

5. The aluminum midpiece replaces easily broken glass connections. It enables one rapidly to convert the straight siphon or lavage tube into one of bulbed type for the purpose of inflating the stomach with air and when expression of gastric contents proves difficult.

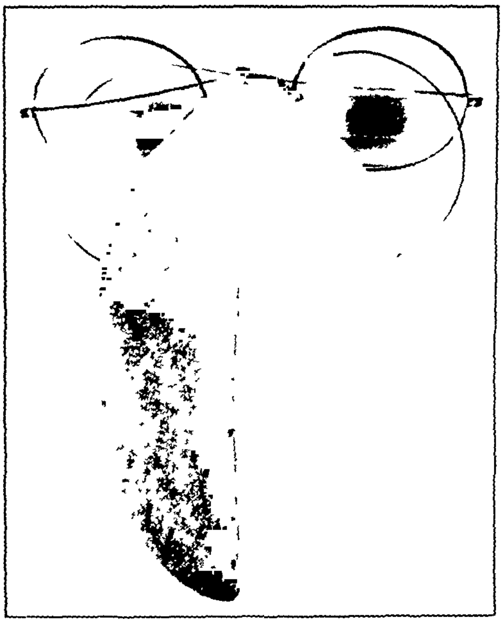
122 South Michigan Avenue.

A SIMPLE DEVICE FOR PROTECTION AGAINST INFECTION IN NOSE AND THROAT EXAMINATIONS

J. F. CROUCH AND C. A. CLAPP, M.D., BALTIMORE

Most devices which are used by the physician to lessen the danger of infection during examinations of the nose or throat are either so uncomfortable or so inconvenient that they are infrequently used. A very simple device which we have used with great satisfaction for several years consists of a pair of Jumbo-sized steel or aluminum spectacles with either plano or one's own correction for the lenses. To the nose-piece is fastened a piece of aluminum sheet which is bent to a V shape to allow room for the nose and extends downward to cover the mouth.

It serves to protect the eyes, nose and mouth from any spray and its great convenience in putting on or off, together with the ease with which it may be sterilized by boiling, would, I believe, make it popular with many.



Device for protection against infection in nose and throat examinations.

513 North Charles Street.

APPARATUS FOR INTRAVENOUS INJECTION OF NEOSALVARSAN IN CONCENTRATED SOLUTION

DAVID GEIRINGER, M.D., NEW YORK

Instructor in Genito-Urinary Surgery and Syphilis, Post-Graduate Medical School

This apparatus is recommended for the intravenous administration of neosalvarsan according to the method of Ravaut.

It consists of two 20 c.c. record syringes (*A* and *B*), two pieces of rubber tubing 3 inches long (*C, C*), one piece of tubing 1 inch long (*E*), a two-way valve (*D*) and a coupling for the needle (*F*).

---

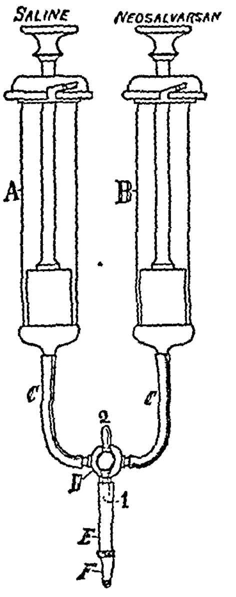
[1] These tubes are Goodyear make.

The syringe *A* is filled with normal saline. Syringe *B* is filled with the neosalvarsan solution, which is prepared by dissolving 0.9 gm. in 20 c.c. of freshly distilled water at room temperature. If smaller doses are used, correspondingly less water is employed.

Syringe *B* being filled with the neosalvarsan solution, it is connected with *one* inlet of the valve *D* by means of the rubber tubing *C*. The air is expelled by advancing the piston into the barrel until some of the solution escapes from the outlet of the valve. The handle of the valve should be in position 2.

Next, the handle of the valve is swung in position 1. The syringe *A* is filled with normal saline and connected with the valve *D*. The coupling and tubing are attached to the outlet of the valve. The air is expelled by injecting the saline into the tubing until it escapes from coupling *F*.

The needle, having been inserted into the vein, is connected with the syringes by means of the coupling *F*. The normal saline is first injected to determine if the puncture has been properly made. Usually 2 or 3 c.c. suffice. If the saline flows satisfactorily, the handle of the valve is swung back to position 2; this opens the way for the neosalvarsan, which is then very slowly injected, consuming from about five to eight minutes.



Convenient apparatus for the intravenous injection of neosalvarsan in concentrated solution.

The object in using the saline is to avoid injecting the neosalvarsan around the vein into the subcutaneous tissues, causing painful infiltrations which persist for a long time. Even in the hands of the most skilful, the needle sometimes pierces both walls of the vein or has not penetrated deeply enough, allowing the escape of the solution into the surrounding tissues.

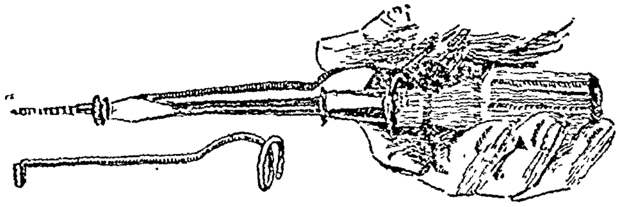
This apparatus is a very simple one and can be assembled at home. The valve can be obtained from any instrument dealer, while a No. 12 soft-rubber catheter suffices for the tubing. It can be used with any needle.

1186 Madison Avenue.

AN INEXPENSIVE SCREW-HOLDER FOR USE IN BONE-SURGERY

Gilbert L. Bailey, M.D., Oak Park, Ill.

A simple and inexpensive device for holding a screw in applying Lane bone-plates or fixing detached fragments of bone may be made of No. 13 copper-plated steel spring wire which can easily be bent and attached to an ordinary screw-driver, as shown in the illustration. The whole apparatus costs thirty cents and a little time, and I have found it of service in many bone cases.



Screw-holder for use in bone-surgery.

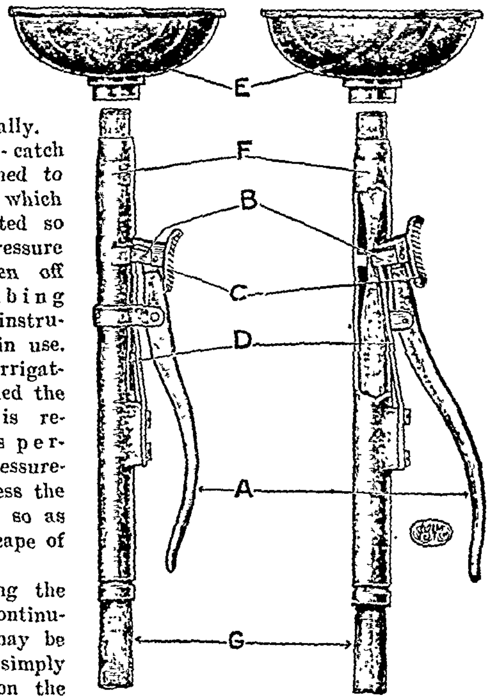
The wire clip holds the screw until it is well started in the desired direction in the drill-hole prepared for it and it is released by pressing the wire with the thumb at the handle.

IMPROVED CUT-OFF: A MODIFICATION OF THE INSTRUMENT USED WITH THE VALENTINE IRRIGATOR

S. Byron Goldsmith, B.S., M.D., Philadelphia

The accompanying illustration is that of a device which I have had constructed to facilitate urethral irrigations. It is a modification of the shut-off used with the Valentine irrigator. In irrigating the anterior urethra with the Valentine apparatus I found it difficult to manipulate for the reason that two hands are required to stop the flow of fluid after each washing. My own instrument requires the use of only one hand as the fluid can be shut off or turned on by simply operating the handle (*A*).

Within the metal casing (*F*) is a pressure-bar (*B*) which compresses the rubber tubing (*G*) by means of a strong steel spring (*D*). To allow the fluid to flow the handle is pressed down, thereby taking pressure off the tubing. When the anterior urethra is full, or when desired, the handle is released and the flow is shut off automatically.



Improved cut-off; a modification of the instrument used with the Valentine irrigator; *A*, handle; *B*, pressure-bar; *C*, thumb-catch; *D*, spring; *E*, shield; *F*, casing; *G*, rubber tube.

A thumb-catch (*C*) is attached to the handle which can be adjusted so that the pressure may be taken off the rubber tubing when the instrument is not in use. Before the irrigating can is filled the thumb-catch is released. This permits the pressure-bar to compress the rubber tubing so as to prevent escape of the fluid.

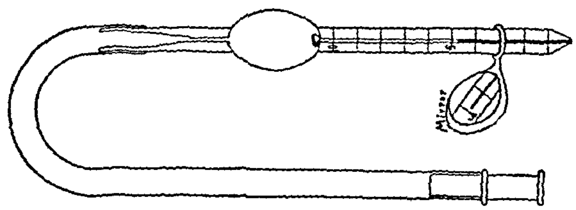
In irrigating the bladder a continuous stream may be obtained by simply pressing on the handle and adjusting the thumb-catch.

247 South Thirteenth Street.

SIMPLE ATTACHMENT FOR BLOOD-COUNTING PIPET

F. B. Schroeder, M.D., Princeton, Ill.

This attachment consists of a small mirror mounted on a split metallic clamp or ring, the bore of which is slightly smaller than the diameter of the pipet. This will allow of free movement of the mirror, which is held in place by the spring action of the split ring.



Mirror attached to blood-counting pipet.

By using this attachment the operator is enabled to observe the gradual ascent of the blood-column, and has no difficulty in obtaining the exact amount.

Therapeutics

PROTEIN POISONING—ANAPHYLAXIS—URTICARIA

(Continued from page 379)

DRUGS WHICH CAUSE ERUPTIONS

Urticarias, erythemas and scarlatiniform eruptions may be caused by belladonna, salicylic acid and arsenic or any of their salts or preparations, antitoxin, many of the volatile oils and drugs containing them (as copaiba, santal oil, turpentine), some of the synthetic compounds (as antipyrin, sulphonal, etc.), chloral, quinin and its salts, and opium and any of its alkaloids or preparations. These eruptions appear in some patients after a single therapeutic dose of any of these drugs; in others only when the drug is pushed, or when it has been given for some time. The frequency of idiosyncrasy against these drugs follows about the order in which they are named. Arsenic will rarely cause an eruption, unless it is pushed to full physiologic action. Some patients acquire a drug tolerance and no subsequent eruptions occur after the first dose or two. This is typically true of some persons who are susceptible to quinin.

Unless the drug is being pushed to full physiologic action with a definite object or a tolerance is expected and desired or the discomfort is unimportant, the drug should be stopped, a cathartic given, and soothing, bland mucous membrane sedatives should be administered, such as bismuth subcarbonate, sodium bicarbonate, milk of magnesia or slippery elm or flaxseed infusions. Even milk and starch-water are sometimes very efficient sedatives to the mucous membrane of the stomach and upper intestine if it has been irritated by a drug. Of course, it is possible that the drug has caused anaphylaxis and the irritant is already in the blood. Then the treatment consists of large amounts of water, a bland diet, alkalies such as potassium citrate, large doses of sodium bicarbonate, and perhaps calcium in some form.

Bromids and iodids frequently cause skin eruptions, occasionally after the first dose, but generally after a series of doses. An eruption quite generally occurs if these drugs are at all continuously given. Some patients, like epileptics or syphilitics, who are given large doses of bromids and iodids for a long time, become tolerant and do not have the skin eruptions, unless the dosage is very large. The iodid eruption is likely to be papular, but is rarely pustular. The bromid eruption is papular and frequently pustular, and the bromids may cause serious skin eruptions. It is sometimes thought that when arsenic is given coincidently with bromids this troublesome eruption is less likely to occur. It also should be remembered that if sodium chlorid is removed from or greatly reduced in the diet of the patient, such large amounts of bromids as were once given are unnecessary. Therefore, the eruption is less likely to occur. The iodids cause eruption less often than the bromids. The eruption from either drug rarely causes itching, but it takes some time for the eruption to disappear, even when the drugs have been discontinued.

The treatment of these eruptions is to stop the drugs, if possible, to cause thorough bowel elimination, to give hot baths or body bakes or electric light baths, and massage, as all tend to promote a more healthy condition of the skin. In fact, the bromid eruptions are less likely to occur if the skin is frequently cleansed and massaged during administration of large doses of the drug.

FEBRICULA

Some short-lived feverish conditions are still termed in medical books "febricula"; still, such a term only means an undiagnosed condition. A slight fever lasting but a day has been termed ephemeral; lasting several days, a febricula. Probably the majority of the feverish attacks which occur more frequently in children are due to some protein poisoning combined with an intestinal upset, and the condition caused is an anaphylaxis. They may be abortive attacks of an exanthem, or, in children, short attacks of glandular fever. They are not infrequently caused by a folliculitis of the nasopharynx, which not being readily seen, is not diagnosed. Inflammation of the adenoid tissue in this region may also cause a febricula. Such patients generally recover rapidly under any treatment, but, if possible, a diagnosis should be made and the proper treatment given.

URTICARIA

It is astonishing that most books on medicine give no description of this condition or of its treatment, though they mention it as a symptom in certain conditions, such as liver disturbance, etc.; but its discussion should be no more limited to books on diseases of the skin than the eruption of measles should be. Urticaria is not a skin disease, although it may be aggravated by certain skin conditions and perhaps also developed by certain disturbances, either vasomotor or of the nervous system.

The name "giant urticaria," sometimes used as a synonym for angioneurotic edema, should be reserved for serious large and changeable localized swellings. An angioneurotic edema may occur frequently or be present every morning, in a patient's hands for instance, but ordinarily carries with it no probability of danger. When it is distinctly localized and does not move from place to place, it may be due to a neurosis of the vasomotor system causing a local dilatation and exudate, with perhaps associated contraction of other vessels. It is a chronic condition and requires long-continued neurotic and nutritional treatment of the patient, although some gastro-intestinal disturbance may be present. Giant urticaria, on the other hand, is a serious, dangerous affection, especially if it attacks the face and mouth, as, when present, it is likely to do at any moment, and dangerous swelling in the throat and larynx may occur. This condition should be treated energetically, and the patient should be under close observation.

The treatment of giant urticaria is catharsis with calomel and saline cathartics; a milk diet, if milk agrees with the patient; or a plain water diet; or a cereal diet. Calcium should be given, and alkalies in large doses. Occasionally, large doses of quinin, such as 60 cg. (10 grains) twice a day, or good-sized doses of antipyrin, as 1 gm. (15 grains) three times a day, have seemed almost specific. Atropin pushed to physiologic action is sometimes of value. The exact cause of this serious condition has not been determined. Doubtless, however, it is anaphylactic and due to protein poisoning.

The causes of simple urticaria are food (protein) poisoning, intestinal parasites, poisoning by certain drugs, disturbances of the liver or kidneys, gout, conditions associated with an increased amount of uric acid in the urine, constipation, an abnormally dry skin, and, in fact, anything that impedes normal elimination. Circulatory disturbances, especially when combined with high blood-pressure or arteriosclerosis, may be factors in causing urticarial eruptions.

Urticaria may occur, however, from almost any feverish condition or from any infection, and simply becomes, then, an added symptom. Most frequently urticaria is the most important symptom, and from its intense itching is the cause of the patient seeking medical advice.

The treatment of simple urticaria has been suggested, namely, catharsis, a limited milk or cereal diet, large amounts of water, the administration of alkalies, such as potassium citrate in 2 gm. (30 grain) doses, given four or five times in twenty-four hours, or some other alkali, if preferred. Potassium citrate may be given as follows:

		Gm. or c.c.		
℞	Potassii citratis	40	or	℥ i
	Aquae gaultheriae	200		fl℥ v

M. Sig.: Two teaspoonfuls, in water, every four hours.

If it is known that the stomach and intestines have been irritated, bismuth subcarbonate and sodium bicarbonate should be administered, and, if the patient does not quickly recover, some form of calcium.

The patient should be kept cool. Thin and nonirritating underwear should be used. If the patient is a child or one in whom the condition tends to recur, linen or silk underwear should be worn. Warm baths, the water made alkaline with sodium bicarbonate, are soothing to urticarial patients, and will relieve the itching. The skin should not be rubbed, but should be mopped, lest the drying process cause irritation and more itching. The localized spots may be sprayed with alcohol, cologne, or even mild acid applications, such as vinegar. Phenol solutions have long been used to dull the irritability of the peripheral nerves; a 2 per cent. solution, with or without glycerin often suffices, as:

		c.c.		
℞	*Phenolis liquefacti*	4		♏ xlv
	Glycerini	25	or	flʒ v
	Aquae menthae piperitae ....q. s. ad	200		fl℥ v

M. Sig.: Use externally as a lotion.

[The preceding should be well shaken and should be labeled as poison.]

Sometimes such applications as "extract of witch-hazel" or a bland oil like almond oil will be soothing to the irritated skin. If the urticarial spots are not in large numbers, such applications as camphor or chloral, with or without menthol, are often valuable, as:

		Gm. or c.c.		
℞	Camphorae			
	Chlorali hydrati .....āā	2	or	ʒ ss
	Glycerini	25		fl℥ i
	Alcoholis........q. s. ad	100		fl℥ iv

M. sig.: Use externally. [Shake, and label as poison.]

		Gm. or c.c.		
℞	Camphorae			
	Chlorali hydrati .....āā	2		ʒ ss
	Mentholis	1	or	gr.xx
	Glycerini	25		fl℥ i
	Alcoholis........q. s. ad	100		fl℥ iv

M. sig.: Use externally. [Shake, and label as poison.]

Various dusting powders are often of benefit, especially in children suffering from this condition. The simplest is powdered starch or a talcum powder. Sometimes stearate of zinc, with or without menthol, is of value as tending to adhere to the region that is irritated.

When urticaria continues or recurs, as it does occasionally in its milder forms, the whole physical condition, diet and personal hygiene, of the patient must be very carefully investigated. Some wrong condition will be found and when it is corrected the disturbance will disappear. Especially must the intestinal digestion be studied and the urine tested for indican. If constipation or indigestion is sufficient to cause indican to appear in the urine, measures to prevent the absorption of the irritants will generally cure the urticaria. Occasionally in young or older persons in whom a high tension or arteriosclerosis has begun or who have insufficient kidneys, conditions of the skin exist that cause temporary reddening, and perhaps itching, with the least irritation.

The skin may be so hypersensitive as to allow of what is termed "dermographia." This condition is a pseudo-urticaria, and the treatments that tend to relieve urticaria will generally relieve this condition.

When there are angioneurotic edemas, a diminution of the sodium chlorid in the food will often be a valuable adjunct to the other treatment inaugurated. This is especially true if the kidneys are at all insufficient.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES."

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN, IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

SEROBACTERINS.—Serobacterins are emulsions of bacteria which have been treated by the application of the corresponding specific immune serum.

Actions and Uses.—Bacteria so treated are supposed to contain specific amboceptors so that immediate union with the complement of the patient's serum is said to occur. Hence, their action is supposed to be more rapid than that of ordinary vaccines. They are also said to be free from the negative phase and the general and local reactions produced by ordinary vaccines.

The immune serum is obtained from goats or other animals that have been treated by the injection first of dead and later of living cultures of bacteria until the blood-serum shows a high titer of agglutinins, opsonins and other specific amboceptors. The bacteria are treated by mixing a filtered emulsion of twenty-four hours' growth of the bacteria on agar, the bacteria having been killed by heat, with the corresponding immune serum. The mixture is left for twenty-four hours at laboratory temperature (not exceeding 24 C.) with frequent shaking. Sufficient sterile saline solution is then added, and the mixture centrifugated for from five to six minutes. The supernatant fluid is removed, more saline solution added and the mixture again shaken and centrifugated. The supernatant fluid is again removed, and the bacteria are counted and standardized in the ordinary way. Since there is a possibility of the living bacteria producing infection, the sensitized bacteria should be killed either by heat or by disinfection.

Tests.—Complement-fixation tests have been applied for the purpose of ascertaining the extent of combination of the amboceptors of the serum with the bacteria. This seems to be the best available method, but a reliable quantitative method is still to be worked out.

H. K. Mulford Co., Philadelphia.

Staphylo-Serobacterin Mulford.—(Sensitized Staphylococcic Vaccine.)—Each package contains four syringes of Staphylo-Serobacterin graduated as follows: syringe A, 500 million killed sensitized staphylococci; syringe B, 1,000 million killed sensitized staphylococci; syringe C, 2,000 million killed [illegible]; syringe D, 4,000 million killed sensitized [illegible]

Strepto-Serobacterin Mulford.—(Sensitized Streptococcic Vaccine.)—Each package contains four syringes of Strepto-Serobacterin graduated as follows: syringe A, 250 million killed sensitized streptococci; syringe B, 500 million killed sensitized streptococci; syringe C, 1,000 million killed sensitized streptococci; syringe D, 2,000 million killed sensitized streptococci.

Typho-Serobacterin Mulford.—(Sensitized Typhoid Vaccine.)—Each package contains four syringes of Typho-Serobacterin graduated as follows: syringe A, 250 million killed sensitized typhoid bacilli; syringe B, 500 million killed sensitized typhoid bacilli; syringe C, 1,000 million killed sensitized typhoid bacilli; syringe D, 2,000 million killed sensitized typhoid bacilli.

PROTEINS AND NUTRITION

In an exceptionally stimulating address before the New York Academy of Medicine, which was reported in some detail in THE JOURNAL,[1] Graham Lusk remarked, quite in harmony with the up-to-date ideas of nutrition, that proteins are especially valuable if they contain an array of constructive units, which, when reunited in the body, form body proteins. Proteins in which one or more of the necessary units or *Bausteine*, as they are now frequently designated, are lacking, can never be reconstructed into perfect body proteins. Professor Lusk adds that such inferior proteins are found in plants. Plant proteins are reconstructed by herbivorous animals into beef proteins, and thus, we are assured, beef proteins attain a higher biologic value than plant proteins. "There can be no doubt, in view of the results of experiment, that meat, fish, milk and egg proteins possess superior value to the vegetable proteins."

It is quite true, as physiologic chemists have demonstrated, that certain proteins, like gliadin and zein, of plant origin, are deficient in some of the groups that characterize the so-called "complete" proteins. Furthermore, we may be prepared to believe from the nutrition experiments notably of Abderhalden, Osborne and Mendel[2] that the animal organism is incapable of synthesizing some of the amino-acid units like tyrosin, tryptophan and phenylalanin *de novo*. Nevertheless, one cannot refrain from the inquiry whether any sweeping condemnation of the plant proteins in the sense here discussed is in reality justified. Whence do the animals that furnish us with beef and milk and egg foods derive some of these essential units if not from plant sources? Until evidence to the contrary is forthcoming we must assume that the herbivorous animals are quite as incompetent to synthesize certain of the units needed for their body proteins as is man. Will it ever become possible for man to obtain all the essential components conveniently or economically directly from the plant sources in ways that are not at present feasible?

A new field for consideration is opened up by the suggestion of Friedenthal, to which we referred last week,[3] that by suitable comminution of those parts of plants which are rich in protoplasmic constituents it may be possible to furnish, in a more available form, types of nutrients in the green vegetables which evade digestive usefulness in the current dietary practices. The vegetable proteins about which, thanks especially to the work of T. B. Osborne and his collaborators in this country, we are best informed, have been derived largely from the reserve tissues of plants — seeds, etc. Not until more facts are available about the proteins of other parts of plants will any final pronouncements of physiologic values be completely justified. Only in very recent times has the protein of the potato been disclosed as a food material of unexpected nutritive efficiency.[4] We are not advocating vegetarianism, but we believe it is too early to foresee what a more extensive investigation in the domain of plant-protein chemistry may disclose. With the growing scarcity and increasing cost of animal products, it behooves us to study exhaustively every scientific means by which the necessity of securing the essential nutritive units through the expensive intermediation of the plant-eating animals may be obviated. Hitherto some of the vegetable products have been considered by physiologists almost entirely from the point of view of their significance as accessories to the dietary of man. The investigations of Strauch,[5] which indicate that even the green parts of plants notably rich in indigestible cellulose may become nutritively useful to man, may lead to new discoveries. Dietary prejudices are slow to be overcome, though it must be admitted that not infrequently they conceal unsuspected elements of physiologic wisdom.

A FOREIGN IMPRESSION OF AMERICAN HOSPITAL SOCIAL SERVICE

There is a certain satisfaction to be derived from the praise, however qualified it may be, that comes to us from foreign shores. This is particularly true with respect to things medical, in the organization and conduct of which America has, as yet, done little more than serve an effective apprenticeship. Germany has so long been held before our eyes as a model of the best in everything pertaining to the activity of the physician and the therapeutic world in which he lives, that a word of commendation from German sources is gratifying. The development of the system of hospital social service, introduced at the Massachusetts General Hospital in Boston in 1905 and since then widely followed throughout the larger cities of the United States, has lately been pleasingly referred to in a magazine devoted to the interests of women in Germany. Mrs. Strauss,[1] wife of the Berlin clinician Prof. Hermann Strauss, calls attention to the evolution of the system of hospital service in this country, its aims and accomplishments, and contrasts it with the less progressive beginnings which are to be found in the hospitals of Europe. We must confess that there is much in her complimentary review that deserves to be brought forcibly to the attention of American women to whose care the execution of these non-medical aspects of hospital activity must inevitably be committed.

Social service has been defined as the application of sound common sense to the end of making the sick well. To this we may add that it is necessary also to keep them well and capable of earning a living, and to avert any recurrence of disease. Besides the physician, who is brought into the closest contact with a patient, few persons realize what manifold factors play on the life of the sick — particularly the needy sick or those on whom others are dependent — and hamper the progress of returning health by the mental influences which they exert on the patient. It thus becomes the duty of the social service worker to investigate the conditions of living and employment, the family relationships and responsibilities of those who have succumbed to severe illness, and by assuring suitable care and protection to the family, uninterrupted maintenance for a threatened home, or the continuance of a wage-paying employment, to bring healing comfort to the helpless. The physician needs no demonstration of the helpful therapeutic effects which follow the establishment of "peace of mind" in a worried patient; and frequently the establishment of a correct diagnosis is facilitated on removal to a hospital by the patient's relief from the mental strain due to his environment and obligations. Other features of enforced confinement in the sick-room also demand the grateful ministrations of the social-service devotee. The patients need to be entertained and encouraged, and to have occupation for the long hours of convalescence. They need, not infrequently, to be prepared for the new occupations sometimes made necessary by injury or the ravages of disease. Their life after release from the hospital must often be completely altered to meet new conditions.

Mrs. Strauss points out that the universal workingman's insurance and compensation acts introduced by the German government have rendered certain features of the hospital social service of less immediate necessity in Germany. This entire field of social and humanitarian endeavor has only begun to be cultivated. Successful methods have yet to be developed to meet constantly changing economic conditions and hygienic innovations. The day must come when every American hospital will possess its social service department.

A NEW METHOD OF INVESTIGATING THE CIRCULATING BLOOD

There are numerous substances, both among those which take part in the normal metabolic transformations of the organism and among those which are present by some fortuitous circumstance, that traverse the body in the circulating blood in quantities too small to be isolated or measured satisfactorily. The rapidity with which compounds that enter the circulation again escape, either by transference to the tissues or by excretion through various channels, has hitherto made it almost impossible to follow them in their migrations in the body. In various discussions regarding the fate of absorbed amino-acids, for example, we have pointed out how difficult it has been until quite recently to secure *competent evidence that these protein derivatives actually* ever pass the alimentary barrier and circulate as such; for at any moment a given specimen of blood withdrawn at any point of either the portal or systemic circulation could contain at best only traces of the substances searched for. In the course of hours the continually renewed blood-stream can, of course, carry very large quantities of products from one region to another in the body, though at any moment the concentration of the material in question in the blood may be exceedingly small. The removal of large specimens of blood from living persons for analysis is not compatible with normal functioning; hence such a procedure is likewise precluded. Physiologists have time and again conjectured that certain compounds must arise as intermediary products in the transformations of the ingesta in metabolism; but owing to the inherent difficulty of detecting them, as just rehearsed, it has been impossible to verify the hypotheses. For the most part it has been necessary to content ourselves with a definite appreciation of the beginning and the end, with the intake and the final output product, and to test the theory of the mechanism of this conversion by indirect modes of experimentation. There are few physiologic substances, not to mention abnormal components of the organisms, for which we are able at present to describe the chemical form in which they travel in the body. The physician who administers a drug is in many instances left to judge by somewhat indefinite responses whether or not it has penetrated to the tissues or organs that he has hoped to influence; and the pharmacologist entrusted with a more accurate and reliable determination of the same question has been obliged in many instances to depend on criteria scarcely less crude. Particularly in the case of agents which act in very small dosage it is rarely possible to be certain that the drug actually enters the circulation or that a given concentration of it is distributed, unless some definite response, like an obvious cardiac, neuromuscular or secretory response, is elicited.

At the International Medical Congress in London last summer and later at the International Physiological

---

[1] Strauss, Elsa: Soziale Fürsorge in amerikanischen Krankenhäusern, Monatschr. *Die Frau*, 1913, xxi, No. 3.

Congress in Groningen, Abel, Rowntree and Turner[1] of the Johns Hopkins Medical School gave a brilliant demonstration of a method which will remove from the flowing blood traces of substances present in only minute quantity at any one time. It consists of a process by which the blood of a living animal may be submitted to dialysis outside the body, and again returned to the natural circulation without exposure to air, infection by micro-organisms, or any alteration that would necessarily be prejudicial to life. The Baltimore investigators have referred to the method as "vividiffusion." Essentially, it consists in connecting an artery by a cannula to a tube or series of tubes made of celloidin or other suitable dialyzing membrane and immersed in a saline solution or artificial serum. The return of the blood to the animal's body is provided for by another cannula attached to a vein. In this way the blood leaving the artery flows through a perfectly closed system and returns to the body within a minute or two, while the diffusible substances which it contains can pass out, more or less rapidly, through the walls of the tubes. The condition is not widely different from what may be conjectured to prevail naturally in certain regions of the intact circulation, except that in the artificial schema the products of diffusion can be withdrawn and examined at will. As an instance of what can be accomplished, it may be cited that an anesthetized dog was kept alive during a dialyzing period of sixteen hours, with about one-third of its blood outside the body.

Experience thus far gathered indicates that this process of "vividiffusion" may be allowed to proceed for several hours without inducing any untoward effects or injuring the animal in any way. The blood is then returned completely to the donor. The apparatus has been termed an artificial kidney, because it can remove certain products from the circulation precisely as does the natural kidney. It differs from the latter in that it makes no distinction between the diffusible constituents.

Any component like sugar, etc., can be retained, however, by a simple expedient. When foreign substances like salicylates are introduced into the individual they can be recovered from the diffusate quite as readily and in as large amounts as those which are normally removed by the renal excretory apparatus. The fact that the application of the apparatus is not prejudicial to life leads the investigators to suggest the more remote possibility that during numerous toxic states in which the eliminating organs, more especially the kidneys, are incapable of removing from the body at an adequate rate, either the native or the foreign substances whose presence in excess is detrimental to life processes, the vividiffusion method may find application. Human therapeutics might thus be able to provide a substitute in such emergencies and tide over dangerous crises.

For the present the value of the method consists in the light which it promises to shed on the little-known diffusible substances normally present in the blood and on the nature of certain intermediary stages of metabolism. A field of investigation is further opened in the comparative study of the blood flowing to and from various organs with reference to the substances which they extract from, or add to, the general circulation. The possibility of thereby detecting the nature of some of the internal secretions or active principles of glandular organs at once is suggested. Now that a procedure is available for accumulating the non-protein nitrogenous constituents of the blood other than urea in any desired amount, we may look forward to details which will give a new picture of the composition of the circulating fluid of the body in health and in disease.

"RELIGIOUS DAILY" RESORTS TO FALSEHOOD

By this time the medical profession and the public have become thoroughly familiar with the fact that the lie indirect is the favorite tool of the antivaccinationist, the antivivisectionist, and all the rest of the militant perjurers who misdirect the ideas of their followers and who attempt to mislead the public. Unfortunately, it is not so easy for the layman to recognize this form of deceit, and hence the success of this method in leading him astray. The person who so garbles a quotation that even the fair-minded reader is misled into believing the author to stand for things that he really most strongly opposes can be ranked only with the most contemptible of moral delinquents. A typical and most pernicious example of this repulsive form of dishonesty was perpetrated by the *Christian Science Monitor* of Friday, January 23, and marked copies of this publication have been scattered with prodigal liberality throughout the country. We are not informed what unselfish philanthropists furnished the necessary funds to finance this broadcast distribution, but evidently there are persons or organizations willing to spend money in an attempt to convince the public that consumption is not dangerous.

The article is based on our editorial of January 3, reviewing the address of Dr. E. R. Baldwin, in which he emphasized the importance of infection in childhood in the production of pulmonary tuberculosis, and expressed the conviction that there is very little danger of adults acquiring a new infection from contact with consumptives. By quoting from this editorial with quotation marks, carefully omitting essential qualifying phrases, and then drawing his own unwarranted conclusions, the writer in the *Monitor* skilfully conveys the impression that the medical profession has finally determined that tuberculosis is not a transmissible disease, that it is a rank waste of public money to build hospitals for consumptives, that the publicity campaign "was ostensibly intended to warn the public against the ravages of the disease," and that it "has served only to spread in the thought and hearts of hundreds of thousands a paralyzing fear that never should have been created."

---

[1] Abel, J. J.; Rowntree, L. G., and Turner, B. B.: Removal of Diffusible Substances from the Circulating Blood by Means of Dialysis, Tr. Assn. Am. Phys., 1913; the details are published in Jour. Pharm. and Exper. Therap., 1914, v, 275.

We print below the quotation, not as printed in the *Monitor,* but resupplying in brackets the very essential phrases which the garblers so carefully left out.

"Adults are very little endangered by close contact with open tuberculosis, and not at all in ordinary association. [Childhood is the time of infection, youth the time of superinfection, and that from extension of the primary disease.] Qualify these statements as we may, it is time for a reaction against the extreme ideas of infection now prevailing. There has been too much read into popular literature by health boards and lectures that has no sound basis in facts, and it needs to be *dropped out or revised.* [More protection of children and better hygiene for adults are logically demanded, but beyond this] the preachments about the danger of infection to adults in the present state of society are without justification from an experimental standpoint. [The statements which we have quoted] represent not one man's views, but what seems to be the growing conviction of [many of] the most progressive and thoughtful students of tuberculosis at the present time."

As will be at once evident, the elisions in brackets entirely alter the statements made by Dr. Baldwin. No one capable of understanding the paragraph as given in full would see in it any grounds for attacking the building of tuberculosis hospitals, or of reducing in every possible way the spread of tubercle bacilli, especially in the home and in public places, where children, with resistance as yet not developed, may readily acquire an infection more extensive than they can possibly overcome. Yet, in the year 1914, with the enormous reduction in the tuberculosis mortality an absolutely established fact throughout the civilized nations following sanatorium treatment and public health methods for restriction of the disease, there are still persons whose minds are so warped and atrophied by religious fanaticism that they would attack and endeavor to abolish all these safeguards of the health of both sick and well. And in their efforts to do so, they do not hesitate to misrepresent and deceive their readers and the public.

TOBACCO-SMOKING AND THE CIRCULATION

It cannot be said that there is a dearth of literature on the relation of tobacco-smoking to health. The data available are, however, tinged in large measure with all manner of biases; and even where the subject has been approached with an "open mind," there is no guarantee of sanity in the conclusions which have been reached. The circulatory mechanism of man is continually played on by conflicting impulses, so that the conditions of blood-pressure and pulse-rate that prevail from time to time may be the outcome of regulatory influences and directive forces so diverse and changeable as to defy the powers of immediate interpretation. Here, as elsewhere in medicine, many an error of conclusion has been committed because of inability to distinguish the causal factor from a large number of variable agencies. We recall that R. C. Cabot has rejected the evidence that alcohol, for example, is so potent an influence in causing degeneration of the blood-vessels as has been frequently argued. To quote a recent writer, "in a middle-aged man who has drunk freely, eaten largely and worked hard, it is impossible to say which of these factors is responsible for the degeneration of his blood-vessels." In view of the foregoing it is not strange that Osler should remark that tobacco is another poison about which it is very difficult to get conclusive evidence.

The modern equipment of the clinical laboratory has made it possible to study certain phenomena with a degree of precision formerly unknown. Accurate determinations are incomparably safer guides to convincing conclusions than guess-work impressions, which are still so largely (and necessarily) the characteristic stock in trade of the clinical observer.

Dr. John,[1] in the clinic of Volhard at Dortmund, has made a recent study of the influence of tobacco-smoking on the circulation. The question at issue involves the effect on the blood-vessels of continued smoking to a degree not productive of obviously toxic phenomena.[2] At the outset it may be admitted on the authority of the hygienist Prof. K. B. Lehmann of Würzburg that, aside from the alkaloid nicotin, the other constituents of tobacco-smoke, namely, carbon monoxid, hydrogen sulphid, hydrocyanic acid, pyridin and its homologues, are without toxic importance in the concentration and under the conditions in which they are ordinarily manifested in smoking. The debate on the cigar versus the cigarette, on "strong" versus "mild" cigars remains untouched.

Dr. John's blood-pressure measurements indicate that the smoking of two "medium" cigars evokes characteristic alterations in arterial pressure in typical cases. Even during the act of smoking there may be evidence of undeniable rise in diastolic pressure, and the effect may persist for as long as two hours. The essential feature in the nicotin effect on the vasomotor apparatus consists in a constrictor stimulus to the vessels which results in increased tonus. The behavior of the pulse-rate is variable. Eight or ten Russian cigarettes give a vasomotor result comparable with two "medium" cigars. Cigars of low nicotin content do not produce a recognizable effect on the circulation.

Despite the interfering complications attributable to pressor and depressor influences, which enter in diverse ways into the daily routine, the smoking of from eight to ten cigars, or from twenty-five to thirty cigarettes during the course of the day is by no means negligible, if we may believe the statements made by John. The widely current impression, based in part on experimental investigations, that nicotin can produce vascular alterations in the sense of sclerotic changes is thus confirmed. We may argue as we will that habitual smokers have consumed extraordinary quantities of tobacco over long periods without signs of vascular change, and that it is difficult to believe that tobacco can, as a rule, have any important influence beyond what the ordinary wear and tear of life itself would warrant. Nevertheless, we are in duty bound to take cognizance of careful blood-pressure measurements and to consider seriously the advisability of extreme moderation in smoking, to say the least, in conditions where the familiar untoward possibilities are threatened. Indifference to scientific evidence is an intolerable attitude.

EVASION OF ENTRANCE REQUIREMENTS TO MEDICAL COLLEGES

Those familiar with conditions in some of the medical colleges of Chicago will not be surprised at the "story" which appears this week in our Medical Education Department.[1] The investigation shows that fraudulent credentials of preliminary education, secured through a local institution, have been accepted by a Chicago medical college. The fact that this story centers around one school is merely incidental: the information which led to the investigation pointed quite as much to two other local colleges as it did to the one in question. The acceptance of questionable entrance credentials prevails to a greater extent in Chicago than elsewhere, although makeshifts if not fraudulent devices for admitting medical students whose qualifications are below the standard are employed in probably two or three other cities. Not only are these efforts to nullify the medical practice act or the rules established by state boards dishonest, but also they work a serious injury to the medical student, who is laying a foundation for his life's work. He is led to believe that he has a satisfactory and adequate preliminary training, when he is, in fact, entirely unprepared for the complicated and difficult course in medicine which is to follow. He is permitted and encouraged to enter a medical college with inferior qualifications, when he should be spending his time in securing the proper foundation for his medical course. By the time he has realized his deficiencies, it is too late for him to go back and make up his shortcomings. As a result, he is handicapped throughout his professional career, the medical profession is burdened with another half-trained member and the public is endangered through a physician whose training is not what it should be.

The necessity for thorough preliminary training as a condition for admission to the modern medical college cannot be too strongly emphasized. There may have been a time when a knowledge of the three R's was sufficient for the medical student. That time, fortunately for the public, is past. In recognition of this fact, efforts are now being made by the proper authorities in practically every state to raise the standard of entrance requirements for medical colleges and to require one or two years of college work, in addition to a standard high school course. The medical colleges themselves, in the main, are endeavoring to elevate their own standards. Approximately seventy of the one hundred and six medical colleges in the country are now requiring one or two years of college work in addition to a high school course. In all of the states, a four-year high school course, or its equivalent, is properly regarded as the lowest educational preparation which can be accepted from any prospective medical student. Yet in Chicago some of the medical colleges are not enforcing even this minimum requirement, but are accepting credentials based on little or no actual work. Such a practice is not only an evasion of the law, it is unfair to the medical student, the profession and the public. On whom rests the blame? While the moral responsibility may rest on the colleges implicated, it must be remembered that commercial medical colleges are conducted for gain and not for altruistic purposes, and that so long as such colleges exist, so long as they are dependent for their support on student fees, and so long as no effective control is exercised over them, just so long will such practices continue.

The blame and the responsibility clearly rest on the officials appointed by the state to safeguard the rights and interests of the public in such matters, namely, the state licensing board. This board constitutes the only barrier between the public and the incompetent physician. It is not compelled to adopt detective methods to secure the facts. It is not necessary for it to carry on any lengthy investigation. It can demand detailed information concerning the schools attended and the credentials presented by every student who enters these medical colleges; and it is the only body that can legally make such a demand. Meanwhile, the fact that the conditions referred to exist in Chicago should not be considered a reflection on the recently appointed state licensing board of Illinois. It is hoped that this new board will perform its duty in a conscientious manner, and that the people of the state may not look to it in vain for protection against these credential mills and against illiterate and unqualified physicians.

Tuberculosis in the Army in 1912.—According to the *Army and Navy Journal*, the highest rate for tuberculosis in the army barracks for the calendar year of 1912 occurred at Vancouver and Fort Flagler, Wash. At Vancouver there were twenty-three cases with a rate of 17.87 per thousand; at Fort Flagler, a rate of 13.25 per thousand. Of 273 cases of tuberculosis in the Army in 1912, seventy-three, and in 1911, out of 258 cases, sixty-eight were detected in the first year of service.

Current Comment

KNOWLEDGE VERSUS SUPERSTITION

The statement has been frequently made, by those who are endeavoring to utilize all of our present-day scientific knowledge for the prevention of disease, that Christian Scientists both as individuals and as an organization are doing everything in their power to obstruct the public health movement. This has been strenuously denied by the leaders of this cult. Elsewhere we comment on the dishonorable methods used by the *Christian Science Monitor* to misrepresent the position of THE JOURNAL and of the medical profession regarding consumption. If the garbled and distorted "quotation" which the *Monitor* tried to make its readers believe was taken from THE JOURNAL of the American Medical Association had been given only the circulation which the *Monitor* itself enjoys, comparatively little harm would have resulted. But it develops that the misrepresentation and editorial dishonesty of the *Monitor* was only a part of a carefully conceived plan for misleading the general public. A large number of copies of the *Monitor* containing the discreditable article have been sent broadcast, especially to the newspapers. These were specially printed with heavy black rules at the sides to call attention to the article. How many of these marked copies have been sent it is impossible to say, but copies have been pouring in to the Association office from physicians and newspapers all over the country. With this positive evidence of deliberate and intentional misrepresentation and falsification on the part of the *Monitor*, and of carefully laid plans to give such deceptive material the widest publicity possible on the part of the leaders of the Christian Science Church, it is impossible for this sect to disavow any longer its deliberate purpose to obstruct and hamper in every way possible the campaign for the prevention of disease and the saving of human life. THE JOURNAL of the American Medical Association and the scientific medical profession of the country are perfectly willing to join battle on this issue with the fanatical adherents of reactionary religious beliefs based on antiscientific mysticism. We have no fear as to the verdict of public opinion when the case is tried between triumphant and ever-advancing scientific knowledge on one hand, and superstition and ignorance on the other. This battle has been fought many times before in past ages, and scientific truth has always been victorious. We regret, however, that the ignorance of the *Monitor* on the subject of consumption is equaled only by its lack of editorial honesty, else it would not have attempted the manifestly foolish effort to put THE JOURNAL in a false position by so stupid a device as that of a garbled and mutilated quotation.

THE EARLY HISTORY OF INFANTILE *POLIOMYELITIS*

Dr. Werner Leo[1] of Charlottenburg has recently given an interesting historical summary of the Heine-Medin disease, from which we glean the following facts: The date usually assigned for Heine's original description of the disease is that of his celebrated monograph of 1840, with its memorable illustrations, the second edition (1860) first introducing the term "infantile spinal paralysis" (*spinale Kinderlähmung*). It appears, however, that Heine had already rendered a short but definite report of the disease to the medical section of the Society of German Naturalists and Physicians in 1838, presenting a case in a 12-year-old girl. But even before this, Dr. John Badham[2] of Worksop, England, had published "Four remarkable cases of suddenly induced paralysis in the extremities occurring in children, without any apparent cerebral or cerebrospinal lesion." These are all well-authenticated cases of infantile paralysis in 2-year-old patients, occurring at close intervals of time in the same locality. Three of these cases had been seen by the author's father, the well-known Dr. Charles Badham of London, whose little book of 1808 is the first account of bronchitis, the term having been introduced in his second edition of 1814. Thus the name of Charles Badham is now associated with the original description of two new forms of disease. It appears that Heine, on page 27 of his monograph of 1860, had already noted the possibility of the contagious or epidemic character of infantile paralysis. The next delineations in order of time were those of the French pediatricians, Rilliet and Barthez; but Charcot's masterly description of 1870, with full necropsy,[3] is the most important. In the summer of 1887, O. Medin observed the first epidemic incidence of the disease (forty-four cases) in the city of Stockholm. Flexner's observations on the experimental production of poliomyelitis (1909-1910) and his isolation of the germ (1913) are events of yesterday.

IODIN IN THE THYROID AND PARATHYROID GLANDS

Ever since Baumann first described the occurrence of iodin in the thyroidal tissues speculation has been rife as to the physiologic significance of this element in relation to the gland. The probability of its functional importance would, of course, be decidedly increased if it were demonstrated that iodin is an invariable constituent of the thyroid gland. There are records of negative findings, usually in the case of the thyroids of children, and particularly in the literature of a decade ago. Meantime the methods of detecting minute traces of iodin in animal tissues have been improved so that with Hunter's procedure 0.01 mg. can be approximately measured. Where such delicate methods have been applied the results have commonly given support to the theory that iodin may be expected in all thyroid tissue. On the other hand, the evidence at present available strongly suggests that the parathyroids are devoid of iodin, the traces now and then reported being attributable to contamination with thyroid tissue.[4] This fact, as far as it goes, gives additional indication in conformity with other physiologic evidence, of the differentiation of function between the thyroid and parathyroid.

WELL-MEANING, BUT NOT QUITE SCIENTIFIC

A dairyman at Jamaica Plain, Mass., has the following notice concerning his milk printed on the end of his monthly bills: "From our own herd of tubercular tested cows." One of our readers, to whom such a bill was rendered, suggests that while the information was rather startling, he has reason to believe that the milk in question is of better quality than the milkman's scientific English.

Medical News

ARKANSAS

Personal.—Dr. and Mrs. Corydon M. Wassell, Little Rock, left January 28 for China. Dr. Wassell will be stationed at Wu Chang in the province of Hankow.——Dr. Harry W. Browning, Little Rock, has been appointed assistant division surgeon of the Missouri Pacific and Iron Mountain System to succeed Dr. Melvin E. McCaskill, resigned.——Dr. W. L. Sadler has succeeded Dr. Harry W. Browning as house surgeon of St. Vincent's Hospital, Little Rock.——Dr. Morgan Smith, president of the State Board of Health, has been appointed collaborating epidemiologist for Arkansas, by the Surgeon-General of the United States Public Health Service.

New Officers.—Faulkner County Medical Society at Conway, January 16: president, Dr. George W. Blakely; secretary-treasurer, Dr. Joseph S. Westerfield.——Bowie County Medical Association at Texarkana, Dec. 29, 1913: president, Dr. Benjamin C. Middleton, Point Cedar; secretary-treasurer, Dr. John M. White, Texarkana.——White County Medical Society: president, Dr. Isaac R. Majors; secretary-treasurer, Dr. John L. Jones, both of Searcy.——Crawford County Medical Society: president, Dr. M. S. Dibrell; secretary, Dr. Othello M. Bourland, both of Fort Smith.——Franklin County Medical Society: president, Dr. Thomas B. Blakely, Coal Hill; secretary-treasurer, Dr. Thomas Douglass, Ozark.——Jefferson County Medical Society at Pine Bluff: president, Dr. Thomas W. Woodul; secretary-treasurer, Dr. John T. Palmer, both of Pine Bluff.——Lonoke County Medical Society: president, Dr. John C. Chenault; secretary-treasurer, Dr. John F. England, both of England.——Jackson County Medical Society at Newport: president, Dr. Ira H. Erwin; secretary-treasurer, Dr. Henry O. Walker, both of Newport.——Pulaski County Medical Society at Little Rock: president, Dr. Alexander E. Harris, Little Rock; secretary, Dr. William T. McCurdy.——Arkansas Society for the Prevention and Study of Tuberculosis at Little Rock: director, Dr. Tillman B. Bradford, Cotton Plant.

CALIFORNIA

State Board Appointments.—Dr. Donald H. Currie, San Francisco, U. S. P. H. S., was appointed a member of the State Board of Health, December 20. At the meeting of the board, January 3, he was elected secretary to fill the vacancy by the resignation of Dr. William F. Snow, Sacramento.——Dr. Edward F. Glaser, San Francisco, has been appointed a member of the State Board of Health, vice Dr. Frank K. Ainsworth, San Francisco, resigned.

Personal.—Dr. James F. Peattie has succeeded Dr. Howard C. Massziger, and Dr. Lionel D. Prince has succeeded Dr. Russell C. Ryan of the staff of the San Francisco Emergency Hospital.——In the damage suit of J. B. Cook against Dr. John I. Boyer, Los Angeles, for alleged malpractice, the court decided in favor of Dr. Boyer, January 6.——Dr. Morton R. Gibbons, San Francisco, has been appointed medical director of the State Industrial Accident Commission.——Dr. Albert E. Myers has been appointed assistant in pediatrics in the University of California Hospital, San Francisco.

New Teaching Hospital for University.—The gift of $125,000 by an unknown friend for a children's department has now completed the fund of $615,750 which has been raised for building a new teaching hospital for the University California Medical Department. Among the other principal contributors are John M. Keith of San Francisco, who has given $150,000 in memory of his wife, and four members of the Crocker family, who have given $150,000 in memory of George Crocker, himself the founder of the Crocker cancer research fund of Columbia University. The givers of the George Crocker fund are Mrs. Harriet F. Alexander, $50,000; William H. Crocker, $50,000; Charles Templeton Crocker, $25,000, and Mrs. Malcolm Whitman, $25,000.

Hospital Notes.—The first patients were received at the new Los Angeles Jewish Consumptive Relief Association Sanatorium, Duarte, January 11. Twelve specially constructed tents have been installed. The formal opening of the new fifty-room building will take place this month.——Physicians of Lodi at a meeting Dec. 20, 1913, have decided to build a twenty-room hospital in that city.——The residence of Dr. Arthur A. O'Neil, medical superintendent of the San Francisco Isolation Hospital, was damaged by fire to the extent of $1,000, December 20.——A new hospital is to be built by the Methodists of Southern California, at Los Angeles. The first building to be erected will be 140 by 72 feet, and will be the central building. Two wings will eventually be added, and the complete hospital will represent an outlay of $250,000 and will accommodate 250 patients.

ILLINOIS

New Officers.—Douglas County Medical Society at Tuscola, January 24: president, Dr. I. Newton C. McKinney, Murdock; secretary-treasurer, Dr. Walter C. Blaine, Tuscola.——Perry County Medical Association at Duquoin, January 21: president, Dr. Elmer J. Burch; secretary-treasurer, Dr. Rolla D. Pope, both of Duquoin.

Personal.—Dr. Max C. Hawley, assistant superintendent of the Watertown State Hospital, has been appointed assistant superintendent of the Elgin State Hospital.——The fiftieth anniversary of the wedding of Dr. and Mrs. John P. Riggs, Media, was celebrated January 28, by more than one hundred friends and relatives of Dr. and Mrs. Riggs.

Prevention of Nervous and Mental Diseases.—Action has been taken in Illinois for a campaign of education for the prevention of nervous and mental diseases, according to a bulletin issued by the State Charities Commission. In January, 1914, a committee composed of Dr. H. D. Singer, director of the State Psychopathic Institute; Dr. E. A. Foley of the Jacksonville State Hospital, and A. L. Bowen, at the meeting of the State Hospitals Medical Association with the Chicago Neurological Society, presented a report on "A Practical Campaign for the Prevention of Nervous and Mental Disease." The plan of the committee did not consider sterilization, sex hygiene or eugenics as important remedies, but urged only those measures on which all authorities agree. The campaign of education to be conducted includes the use of space in newspapers for the publication of facts about the Illinois state hospitals; cooperation between the press and state charities; publication in popular magazines of articles written for the laity; compulsory psychiatry in all medical colleges, and psychopathic wards in general hospitals; a system of care for patients after they leave the hospitals, and a system of outpatient service to advise patients in detention hospitals and homes. The report also urges a revision of the commitment laws, so that the insane may not be thrown into jails, or held for trial like criminals.

Chicago

Immigration Station Opened.—The new immigration station at 845 South Wabash Avenue was opened January 28. Dr. Percy L. Prentiss, head of the local Bureau of Immigration, is in charge of the station.

Personal.—Dr. Frances Dickinson has been elected president of the Artcraft Institute Guild.——Dr. Benjamin H. Breakstone has resigned as president of the medical staff of the Maimonides Kosher Hospital.——Dr. Howard L. Beye has been appointed assistant in the department of surgery in the University of Iowa.

Tuberculosis Institute Election.—At the eighth annual meeting of the Chicago Tuberculosis Institute, January 29, the following officers were elected: president, Dr. Theodore B. Sachs; vice-presidents, Dr. Robert H. Babcock and Mr. George W. Perkins; treasurer, Mr. David R. Forgan; secretary, Mr. Sherman C. Kingsley; directors, Drs. William A. Evans, James Alexander Harvey, John Ritter and George W. Webster; Rev. P. J. O'Callaghan, Hon. Harry Olson, Hon. Julian W. Mack, Mr. G. R. Durgan, Mr. H. N. Foster, Mr. George W Perkins.

In the report the directors laid especial emphasis on the conditions in the various sanatoriums in or near Chicago, and pledged the organization to continue fighting for the adoption of all recommendations made by the special tuberculosis committee. The institution will continue to carry on the systematic medical examination and supervision of the health of employees in working-places; the tuberculosis exhibits, which were visited by 112,711 persons in 97 days; the publication of the tuberculosis bulletin and the tuberculosis study circles.

LOUISIANA

State Board Proceedings.—At a meeting of the Louisiana State Board of Medical Examiners, January 14, Dr. Edmund L. Leckert was elected secretary of the board, vice Dr. Arthur Bernard Brown, deceased. The board adopted resolutions testifying to the untiring zeal and constant devotion of Dr. Brown, and expressing regret at his untimely death.

Personal.—Dr. Creighton Wellman, dean of the School of Hygiene and Tropical Medicine of the Tulane University of Louisiana, has found it impossible to continue longer the duties of his position. He has, accordingly, tendered his resignation, which has been accepted. Dr. Wellman contributed services of great value to the university through his aid and counsel in the organization of the School of Hygiene and Tropical Medicine and in many other activities. There will be no interruption in the school and his successor will be selected at an early day.——New Orleans Medical Society, at its meeting January 12, presented Dr. Charles C. Bass with a gold medal in recognition of his successful culture of the germ of malaria.——Dr. Abraham L. Metz completed twenty-five years of service as city chemist of New Orleans, January 2.——Dr. G. Farrar Patton, for ten years secretary of the State Board of Health, has been appointed state registrar of vital statistics.——Dr. Oscar Dowling, superintendent of the State Board of Health, has been appointed collaborating epidemiologist for the state.

MARYLAND

New Surgery Building.—The members of the Woman's Auxiliary of the Methodist Hospital Association, Baltimore, have started a campaign to raise $20,000 for a new surgery building for the Maryland General Hospital.

Personal.—Dr. Howard A. Kelly, Baltimore, sailed for Europe, January 25.——Drs. William H. Welch, Baltimore, and Edgar A. P. Jones, Cambridge, have been appointed members of the State Board of Health.——Dr. Robert L. Keyser, Baltimore, who was operated on for appendicitis at the Union Protestant Infirmary, January 17, is reported to be convalescent.

New Maternity.—A maternity hospital costing $50,000 has been given by Mr. Abraham Mandels, a retired merchant, as a memorial to his brothers. It is to be an adjunct to the Hebrew Hospital and Asylum. Work on the building will begin immediately and be rushed to completion. The new building will be completely furnished and provide twenty beds, every patient having a private room; not only to paying patients but to the poor as well. Dr. Harry Adler, president of the board of directors of the hospital, at whose suggestion the new hospital was given, said in announcing the gift: "The condition of the people on the East side of Baltimore is deplorable, and this is one of the things we hope the new hospital will remedy. In many cases even clean towels could not be found in homes where a child was born. Hereafter we shall be glad to take these needy cases from the tenements and bring the mother to the hospital where she and her child will be given the very best attention. The result will be that not only will the mother benefit but there will be greater assurance for a stronger and better generation in the future." The new building will be modernly equipped and complete in every detail.

Proposed Legislation.—Several bills extending the power of the State Board of Health have been introduced in the general assembly. These provide for the division of the state into sanitary districts and the appointment of deputies in charge of each district, for the more effective control of water-supplies and for the more accurate registration of vital statistics.——Dr. Eugene Jones, Kensington, state senator from Montgomery County, has introduced a bill regarding the sale of bichlorid of mercury. The bill specifies that the words "bichlorid of mercury" shall be blown into the bottle; that the tablets shall have a definite shape, and that the label on each bottle shall bear the word "poison" in prominent letters.——The Board of State Aid and Charities in Maryland has introduced a bill which will place under its control all the hospitals and charitable institutions receiving state aid. Heretofore the duties of this board have been supervisory, but under the new plan the distribution of all state funds to hospital and charitable organizations will pass through the hands of the board.——The State Lunacy Commission has introduced a bill calling for a bond issue of $600,000 to be known as the "Third Insane Hospital Bond Issue." From the proceeds of this issue two modern psychopathic buildings will be completed, one at the Spring Grove State Hospital and the other at the Springfield State Hospital; and, in addition to these buildings, the bond issue will provide for the completion of the State Hospital on the Eastern Shore of Maryland for the Insane; the removal of all patients from the Insane Department at Bay View, the Baltimore Detention Hospital, and the permanent closure of this department.

MASSACHUSETTS

New Leprosarium.—The State Board of Charities has formulated a plan for a new leprosarium at Penikese Island, to cost about $40,000.

Personal.—Dr. and Mrs. Arthur M. Greenwood, Marblehead, sailed for Europe, January 20.——Drs. Frederick L. Lyons and Aubrey J. Collins have been appointed school physicians of Boston.——Dr. James S. Tompkins, resident physician at the Long Island Alms House and Hospital, Boston, has resigned.——Dr. Frederick A. Bartlett, Quincy, has been appointed city physician of Quincy.——Dr. J. Frank Curtin, North Abington, has been appointed medical examiner, vice Dr. Frank G. Wheatley, North Abington, term expired.——Dr. Melvin G. Overlock, Worcester, has been appointed state health inspector for the southern central district of the state.

MICHIGAN

Sanatorium Notes.—Three tent-houses have been purchased for the Detroit Tuberculosis Sanatorium, to be used until the new twelve-room addition to the institution is completed. The new building is to cost $25,000.——The state has appropriated $20,000 for the erection of a tuberculosis sanatorium at Sanford, Midland County. The board of trustees of the State Sanatorium, Howell, has reported to the governor that it cannot purchase land and erect buildings for the amount appropriated by the city, and has asked instructions as to its action in the matter.

Personal.—At the annual meeting of the Michigan State Medical Society in Detroit, January 19, Dr. Frederick C. Warnshuis, Grand Rapids, was reelected secretary-editor, and Dr. D. Emmet Welsh, Grand Rapids, treasurer.——Dr. Charles G. Jennings, Detroit, was given a dinner, January 6, by the medical staff of Harper Hospital.——Dr. Karl B. Brucker, Lansing, has been appointed a member of the State Board of Pardons, succeeding Dr. Frank T. Roach, Newport, resigned.——Dr. and Mrs. DeWitt C. Adams, Detroit, have sailed for Europe.

MINNESOTA

Personal.—Lieut. Reuben M. Pederson, Minneapolis, has been commissioned Major M. C., Minn., and assigned to the First Infantry.——Dr. Olaf J. Hagen, Moorhead, chairman of the State Efficiency Commission and the subcommittee on health and safety, has resigned as chairman, but will retain his membership on the committee.——Dr. Charles H. Zander, St. Paul, has succeeded the late Dr. Eugene W. McCord as a member of the medical staff of the Omaha Employees Benefit Association.

State Board Changes.—At the annual meeting of the State Board of Health held in Minneapolis, January 13, Dr. William A. Jones, Minneapolis, was reelected president and Dr. Burton J. Merrill, Stillwater, was reelected vice-president. The board approved the County Sanatorium Commission, consisting of Drs. John W. Bell, Hennepin County; Myron W. Smith, Goodhue County; Thomas Lowe, Pipestone County, and Alfred L. Vadheim, Lincoln County.——A branch laboratory is to be established by the board at Eveleth, to take care of the increasing work on the Iron Range.——Dr. Egil Boeckmann, St. Paul, has been appointed a member of the board, succeeding Dr. Robert O. Earl, St. Paul.

MISSISSIPPI

Gulfport Made Relief Station.—The United States Public Health Service has directed that Gulfport be made a relief station, and hereafter all American sailors will be given medical attention free of charge at King's Daughters Hospital.

Release from Quarantine.—The American schooner, *Carrie A. Lane*, which has been held at quarantine at Gulfport, because she had come from Brighton, Trinidad, where yellow fever is epidemic, has been released and allowed to enter Gulfport harbor.

Personal.—Dr. William W. Smithson has been appointed superintendent and Dr. R. E. Howard a trustee of the Mississippi Insane Hospital, Jackson.——Dr. Roland H. Cranford, Moselle, is reported to be seriously ill with septicemia in the Hattiesburg Hospital.

NEW YORK

Personal.—Dr. Linsley R. Williams has been appointed first deputy health officer of the state by Dr. Herman M. Biggs who took his oath of office January 21.

Farm for Convalescents.—The West Side Y. M. C. A., which has a farm of several hundred acres 4 miles from Kingston, N. Y., which has been used as a summer camp for boys, is making arrangements to open it for men discharged from city hospitals but who are still too weak to return to work.

Harvey Society Lecture.—The next lecture in the present course of Harvey Society Lectures will be given at the New York Academy of Medicine, on the evening of February 14, at 8:30 o'clock. Prof. J. J. R. Macleod of the Western Reserve University will speak on "Recent Work on the Physiological Pathology of Glycosuria."

Warship Under Quarantine.—The new battleship *Arkansas* is quarantined in the Brooklyn Navy Yard. The 1,000 officers and men are held on the vessel because of a threatened epidemic of diphtheria. Two men had the disease and fourteen others who are suffering from severe sore throats and fever were awaiting developments.

New Seaside Hospital Building.—The construction of the new Seaside Hospital at Rockaway has been begun. The Association for Improving the Condition of the Poor has $257,000 toward the project, which was raised seven years ago after a country-wide campaign. The fund has been held in trust since that time waiting for the city to accept the offer of the association to build and equip the institution provided the city would provide a site and assume ownership and conduct and maintain the hospital. The association hopes to have the institution ready for occupancy by May, 1915. The hospital will be situated on the ocean front, and when the entire plant is completed will comprise a four-story structure fronting on the ocean and eight pavilions, each 138 by 142 feet. The completed hospital will cost about $2,000,000 and will have a capacity of 1,000 beds. The association's gift to the city will include two of these pavilions and part of the main hospital structure, providing for 150 patients. The remainder of the accommodations will be at the disposal of those outside the city who have helped to establish the institution.

Mount Sinai Hospital Annual Meeting.—At the sixty-first annual meeting of the directors of this institution recently held it was announced that Dr. Arpad G. Gerster who had been visiting surgeon for thirty-four years, and Dr. Julius Rudisch who had been visiting physician for thirty-nine years, have retired from active service to become consulting surgeon and physician respectively. Dr. Gerster was presented with a silver tea service and Dr. Rudisch with a silver Greek vase. It was also announced that a plot of ground 175 by 100 feet on Fifth Avenue and Ninety-Ninth Street, just across from the hospital has been donated as a site for the additional hospital building for which a building fund of $1,000,000 has been collected. Half a million dollars is still needed to complete the required amount. The president's report shows that the receipts of the hospital for the last year were $421,384 and the expenditures were $469,892, leaving a deficit of $48,507 which it will be necessary to borrow from the permanent fund. The number of patients admitted during the year was 7,537, or 234 less than during the previous year. There were 5,326 free patients. In the dispensary there were 231,092 consultations, 5,205 less than during the previous year.

New Drug Bill.—The senate committee on Public Health has under consideration a bill to prevent the sale of all habit-forming drugs, except on prescription properly filled out by a practicing physician and by a licensed pharmacist, who shall keep a record of all such sales, the date of sale, the name and address of the physician giving the prescription, and the name and address of the person prescribed for. The bill provides that no prescription shall be filled more than once. In addition it makes it unlawful for any person to sell at retail or to furnish to any person other than a duly licensed physician, dentist or veterinarian, a hypodermic syringe without first receiving from the purchaser an official prescription blank properly filled out. The measure was drawn by Dr. Charles B. Towns of New York City. It makes provision for those who have become so addicted to the use of drugs that to deprive them offhand would be to invite an outbreak of violence, and it also provides that separate quarters shall be maintained in city and county hospitals for the treatment of those addicted to drug habits. It further authorizes local health boards to issue without charge official prescriptions to such persons as have become entitled to the regular administration of these drugs through illness.

New York City

The Crocker Research Laboratories.—It is announced that although the Crocker Research Laboratories which were founded for research work in cancer have been open but a few weeks 5,000 animals have already been inoculated with cancer. Every time a new method of cure worthy of consideration is suggested 100 animals are inoculated with the disease and placed under observation. At present experiments as to the efficacy of radium are being tried, but it is stated that no definite reports will be given out before the end of three years. One of the most important branches of work carried on at the laboratory is that of diagnosis of cases. The records of investigations are preserved and are at the service of physicians who care to use them. Courses of instruction open to physicians will be a part of the work of the laboratory staff.

NORTH CAROLINA

Tuberculous Children Excluded.—The Roann County Board of Health has adopted an order excluding children suffering with tuberculosis from the public schools of the county.

Personal.—Dr. Samuel A. Henley, Ashboro, suffered a loss of $3,000 by fire at his residence, January 21.——Dr. Richard W. Wooten, Kinston, is reported to be seriously ill at his home.——Dr. Samuel P. Burt, Louisburg, who was seriously injured in a runaway accident recently, is reported to be convalescing.

Hospital Report.—The annual report of the James Walker Memorial Hospital, Wilmington, shows that during the past year 1,384 patients were treated, of whom 816 were white and 568 colored. Of the charity patients 185 were white and 470 colored. The expenses of the institution were $40,209.41 and the income was $38,058.37.

NORTH DAKOTA

New Officers.—Sheyenne Valley District Medical Association, at Valley City, January 22: president, Dr. William B. Wanner, Wimbledon; secretary, Dr. Samuel A. Zimmerman, Valley City.

Small-Pox at State Hospital.—For the fifth time since the establishment of the State Hospital at Jamestown, small-pox has appeared in that institution. Twelve cases have appeared, but prompt action of the officers, has resulted in the checking of any further spread of the disease.

OHIO

State Board Withdraws Recognition.—Official information says that at its recent meeting the State Medical Board of Ohio withdrew recognition from the Toledo University Medical Department.

Personal.—Dr. Otto P. Geier, superintendent of Charity and Corrections of Cincinnati, has resigned and will take a long course of study abroad.——Dr. Charles S. Rockhill, Superintendent of the Cincinnati Municipal Tuberculosis Sanatorium, has resigned.——Dr. Emanuel Schwab, Cincinnati, is said to be seriously ill with heart disease, at his home in Walnut Hills.

City Hospital Superintendent.—The results of the Civil Service examination for the City Hospital superintendency were announced Monday, February 2, as follows: Dr. Charles F. Sanborn, Chicago, 80.65 per cent.; Dr. William H. Pritchard, Gallipolis, Ohio, 72.35 per cent.; Dr. Arthur C. Bachmeyer, Acting Superintendent, Cincinnati Hospital, 71 per cent. From these figures, it is reasonably certain that Dr. Sanborn will be the new superintendent of the Cincinnati Hospital. There is a current rumor to the effect that Dr. Bachmeyer will be appointed to fill Dr. Charles S. Rockhill's place as superintendent of the Tuberculosis Hospital.

Saturday Evening Lectures.—The following program of Saturday evening lectures has been arranged to be held at the Experimental Research Laboratory, Broadway, Cincinnati:

January 31, Dr. James M. Ball, St. Louis, "Great Artists and Famous Anatomists." February 7, Dr. Charles S. Rockhill, Cincinnati, "Experiments on Animals Pertaining to Tuberculosis and Hydrophobia." February 14, Dr. C. A. Zwick, "Chemical Experiments on Animals." February 21, Dr. Archibald H. Barkley, Lexington, Ky., "Experiments on Fractures in Animals." February 28, Dr. John W. Vaughan, St. Louis, Mo., "The Production of Anti-Cancer Globulins in Animals." March 7, Dr. Simon P. Kramer, Cincinnati, "Experiments and Their Influence on Brain Surgery." March 14, Dr. John H. Landis, Cincinnati, "Experiments on Animals and Their Influence on Mortality." March 21, Dr. James W. Miller, Cincinnati, "Experiments on Animals in the Production of Diphtheria Antitoxin." March 28, Dr. Luther L. Hill, Montgomery, Ala., "Experiments on Animals in the Development of Heart and Lung Surgery." April 4, Dr. Otto Juettner, Cincinnati, "Experimental Electro-Therapeutics." April 11, Dr. Howard Ayres, "Vivisection and Its Purposes." April 18, Dr. Victor D. Lespinasse, Chicago, "Experiments on Blood-Vessels of Animals and Transfusion of Blood." April 25, Dr. Burrill M. Ricketts, Cincinnati, "Experiments on Animals' Intestines."

PENNSYLVANIA

Personal.—Physicians of Honesdale met at the home of Dr. Robert W. Brady, January 23, and celebrated the fiftieth anniversary of the graduation of Dr. Brady from Albany Medical College.

State Hospital Overcrowded.—On January 29, inspection was made of the State Hospital for the Insane at Norristown, by the officers of the Public Charity Association of Pennsylvania, and it was found that there were too many inmates for the doctors and nurses to have complete oversight of their charges. There are 2,952 patients of whom 1,443 are men and 1,509 women. To accommodate this large number it is necessary to crowd the dormitories and wards.

Facts About Cancer.—A joint meeting of the Twentieth Century Club, Pittsburgh Academy of Medicine, and American Society for the Control of Cancer, was held in Pittsburgh, February 3, at which Dr. James W. Macfarlane presided, and addresses were delivered by Mr. Frederick L. Hoffman, New York; Dr. Edward Reynolds, Boston; Mr. E. A. Woods, Rev. J. Leonard Levy, D.D., Rt. Rev. Bishop Regis Canevin, Mr. John A. Brashear, LL.D., and Rev. Maitland Alexander, D.D.

New Officers.—Medical Society of Northampton County at Easton, January 16: president, Dr. Noah W. Reichard, Bangor; recording secretary, Dr. W. Gilbert Tilman, Easton; corresponding secretary, Dr. Frederick E. Ward, Easton.——Lebanon County Medical Society at Lebanon: president, Dr. John Walter; secretary, Dr. Charles M. Strickler, both of Lebanon.——Perry County Medical Society at Newport, January 14: president, Dr. William T. Morrow, Loysville; secretary, Dr. A. Russel Johnston, New Bloomfield.——Lehigh County Medical Society, eighteenth annual meeting, at Allentown, January 13: president, Dr. William J. Hertz, Palmerton; secretary, Dr. Jacob T. Butz, Allentown.——Cumberland County Medical Society at Carlisle, January 13: president, Dr. William S. Ruch; secretary, Dr. Edward R. Plank, both of Carlisle.——McKean County Medical Association at Kane, January 14: president, Dr. Samuel H. Haines; secretary-treasurer, Dr. James Johnston, both of Bradford.——Indiana County Medical Society at Indiana, January 13: president, Dr. William B. Ansley, Saltsburg; secretary, Dr. William A. Simpson, Indiana.——Bradford County Medical Society at Sayre, January 13: president, Dr. Donald Guthrie, Sayre; secretary and reporter, Dr. Cyrus L. Stevens, Athens.

Philadelphia

New Officers.—Philadelphia Medico-Legal Society, January 27: president, Dr. William T. Hamilton; secretary, Dr. Charles W. Schaubel.

Portrait Presented.—A portrait of the late Thomas G. Morton was presented by Mr. Arthur V. Morton to the College of Physicians, February 4. The presentation address was made by Dr. Morris J. Lewis.

Tribute to Dr. Spitzka.—At the funeral services of the late Dr. Edward Charles Spitzka, held at his late residence, January 15, tributes were paid to his memory by Rev. Charles F. Faguani and Drs. William C. Pritchard and H. E. Brill.

Personal.—Dr. McCluney Radcliffe has been elected ophthalmic surgeon to the Presbyterian Hospital to succeed Dr. George Strawbridge, resigned.——Dr. C. Doane has been appointed permanent resident surgeon at the State Hospital, Shamokin.

Additions to Hospital.—Architects have been selected to draw plans for the additions to St. Mary's Hospital, to be erected at Frankford Avenue and Palmer Street. The additions consist of a five-story and basement wing to be built on Palmer Street, about 170 feet, with another wing along Sepviva Street, 268 feet. The buildings will be of brick, stone and terra cotta, of Renaissance style of architecture, and the construction will be fire-proof.

Outside City Doctors Plan Fight.—Twenty-one of the twenty-five "Visiting Poor" physicians of the Bureau of Charities, who were dismissed last week by Director Wilson, held a meeting January 25, and decided to fight their removal and base their fight for retention on three grounds. The first was that counsels had appropriated $27,000 for the work done by the fifty visiting poor physicians, and that the act of 1892, authorizing such work had not been amended or repealed; second, the right of Assistant Director Wilson to make the dismissals in the absence of Director Neff. The final contention was that the position of Assistant Director Wilson is in jeopardy because he is not a graduate of a medical college.

Hospitals to Have Uniform Accounting System.—A joint meeting of the Efficiency Board of the County Medical Board and the State Board of Charities, was held in the rooms of the state board in the Bulletin Building, January 30, and definite plans for increasing efficiency and reducing the cost of maintenance in city hospitals were discussed. It was decided that a uniform system of accounting, suitable for the fifty-five hospitals, would be the first improvement. Harry S. McDevitt and W. B. Hadley were chosen to investigate every hospital in this city and report at the February meeting. The members of the hospital Efficiency Board are Drs. Edward Martin, Charles B. Penrose, George S. deSchweinitz, Wilmer Krusen and John D. McClain, and Richard Waterman, secretary.

SOUTH CAROLINA

Pellagra Hospital.—A state hospital for the study and treatment of pellagra is to be established under a bill which has been favorably reported by the senate and finance committee. The bill provides for an initial appropriation of $25,000.

Eugenics Bill Killed in Senate.—The state senate, by vote of 22 to 17, on January 14, failed to approve the bill endorsed by the South Carolina Medical Association, which requires the production of medical certificates of freedom from diseases on the part of male applicants before the issue of marriage licenses.

Personal.—Dr. H. R. Black, president of the Spartanburg Hospital, is under treatment in Philadelphia for injuries to his arm received by being thrown from his buggy, January 15.——Dr. Cyril T. Wyche, Prosperity, has been elected speaker pro tem, of the South Carolina House of Representatives.——Dr. Thomas T. Earle has been reelected president and Dr. T. R. W. Wilson secretary of the medical staff of the Greenville City Hospital.

TEXAS

New Officers.—Central Texas District Medical Society at Waco, January 12-13: president, Dr. Selwyn P. Rice, Marlin; secretary-treasurer, Dr. Herschell F. Connally, Waco. The semi-annual meeting is to be held in Hillsboro the second Tuesday and Wednesday in July.——Galveston County Medical Society at Galveston, January 9: president, Dr. Ashley W. Fly; secretary-treasurer, Dr. Lawrence R. Harris, both of Galveston.——Bell County Medical Society at Temple, January 9: president, Dr. Edward J. Burns; secretary-treasurer, Dr. Lewis R. Talley, both of Temple.——San Antonio Academy of Medicine, organized January 5: president, Dr. Charles A. R. Campbell, San Antonio; secretary-treasurer, Dr. Robert A. Roberts.——Tom Green County Medical Society at San Angelo, December 30: president, Dr. Jesse S. Hixon; secretary-treasurer, Dr. Lester C. G. Buchanan, both of San Angelo.——Eastland County Medical Society at Cisco, December 31: president, Dr. William M. Powell; secretary-treasurer, Dr. William P. Lee, both of Cisco.——Johnson County Medical Society at Cleburne, December 29: president, Dr. G. Daniel Strickland, Cleburne; secretary, Dr. Charles L. Edgar, Fort Worth.——Tarrant County Medical Association at Fort Worth, December 22: president, Dr. Joseph A. Gracey; secretary, Dr. Frank G. Sanders (reelected), both of Fort Worth.——Fort Worth Physicians' Club: chairman, Dr. Crittenden Joyes; secretary, Dr. Pierre F. Higgins (reelected).

GENERAL

Students of Epilepsy to Meet.—The twelfth annual meeting of the National Association for the Study of Epilepsy will be held in Baltimore, May 25.

Medical Jurisprudence Organization Incorporated.—The American Association of Medical Jurisprudence has been incorporated under the laws of the State of New York. The membership is to consist of physicians and lawyers. The first annual meeting is to be held in New York City, May 2, under the presidency of Dr. Reynold Webb Wilcox.

Fraternal Election.—At the annual convention of the Phi Delta Epsilon held in New York, recently, the following grand officers were elected: consul, Dr. Murray B. Gordon, Brooklyn; vice-consuls, Drs. Leo S. Schwartz, Brooklyn; Bernard B. H. Aarons, Philadelphia; George Pinēss, Passaic, N. J.; chancellor, Dr. Aaron Brown, New York City; scribe, Dr. Ellis Campus, New York City, and historian, Dr. Irving Gray, Brooklyn.

Porto Rico Physicians Meet.—The annual meeting of the Medical Association of Porto Rico was held in Ponce, Dec. 13-14, 1913, and the following officers were elected: president, Major Bailey K. Ashford, M.C., U.S.A.; vice-president, Dr. Pedro Malaret; secretary, Dr. Jorge del Toro; treasurer, Dr. Jacinto Aviles, and councilor, Dr. P. Gutierres, Igaravidez. The next meeting of the association will be held at Guayama.

Congress on Social Insurance.—The International Congress on Social Insurance will meet in Washington in September, 1915, on the invitation of the United States government. This congress meets biennially, and this will be the first meeting in the United States. The headquarters are in Paris, where a permanent committee carries on the work of the organization between sessions. M. Leon Bourgeois, former Prime Minister of France, is president, and M. Edouard Füster, general secretary. Secretary of State Bryan has announced the appointment of a general committee to make arrangements for the Congress, which includes the Secretary of the Treasury and the Secretary of Commerce and Labor, as well as a long list of prominent persons in the United States interested in sociologic work.

Competitive Examination for Food and Meat Inspector.—Savannah, Ga., has adopted the sensible plan of holding a competitive examination for the position of food and meat inspector for that city, instead of appointing untrained persons because of their political pull. By an ordinance providing for a chief inspector and assistants the mayor is given the power of appointment, but the appointees are to be persons who have passed successfully a competitive examination to be made and held in such manner as is directed by the health officer of the city. In order that persons trained in the duties of food and meat inspectors may be secured for the positions it has been arranged that examinations are to be held in Savannah and Augusta, Ga., Boston, Washington and Chicago, after advertisement in veterinary journals and the posting of notices in the veterinary schools of the country.

Bequests and Donations.—The following bequests and donations have recently been announced:

New England Hospital for Women and Children, Children's Hospital, Boston, and Boston Floating Hospital, each one-seventh of property inherited from his father; Boston Lying-in Hospital, Boston Floating Hospital and Children's Hospital, each one-fourth of any property inherited from his mother, by the will of John Ware Willard, Brookline, Mass.

Massachusetts Homeopathic Hospital, Boston, $50,000, Boston Home for Incurables, $25,000, by the will of Benjamin Leeds, Roxbury, Massachusetts.

Milford (Mass.) Hospital $10,000, to be known as the Bancroft-Day Fund, the income to be used for general hospital purposes, by the will of Mrs. *Lura Bancroft-Day*.

University of Pennsylvania Hospital, $12,000, for the purchase of radium to be used in the treatment of cancer, donation by George H. McFadden, Philadelphia, through Dr. Alfred Stengel.

Philadelphia Home for Incurables, $7,500, for maintenance of a free bed in the cancer annex.

Allentown Hospital, donation of $30.000 for the construction of an operating-room, by Dr. Charles D. Schaeffer.

Tenth Annual Conference on Public Health Legislation and Medical Education.—The tenth annual conference of the Councils on Medical Education and Medical Legislation of the American Medical Association will be held at the Congress Hotel, Chicago, Monday and Tuesday, Feb. 23 and 24, 1914, the sessions to begin at 9 a. m. On Monday will be held the Conference of the Council on Health and Public Instruction, the principal speakers on the program being Dr. William F. Snow, secretary, American Social Hygiene Association, New York City, on "Recent Efforts for Sex Education"; Dr. C. A. Harper, secretary, State Board of Health, Madison, Wis., on "Wisconsin's Experiment in Marriage Legislation"; Dr. J. W. Pettit, Ottawa, Ill., on "Public Education Through the Daily Press"; Dr. W. S. Rankin, secretary, State Board of Health, Raleigh, N. C., on "Public Education Through State and County Boards," and Dr. Frederick R. Green, secretary, Council on Health and Public Instruction, on "Sixty-Seven Years of Legislation." On Tuesday will be held the Conference o Medical Education. At this conference, besides the usu addresses by the chairman and secretary, there will be th following addresses: "Administering the Year in Physic Chemistry, Biology and a Modern Language," by Dr. Richard I Whitehead, Dean of the Medical Department of the Universit of Virginia, Charlottesville, Va. "The Danger to the Maintenance of High Standards from Excessive Formalism," b President A. Lawrence Lowell, Harvard University, Cambridg Mass. "Hospitals and Their Relations to Medical Colleges an the Hospital Intern Year," by Dr. Christian R. Holmes, Dea Ohio-Miami Medical College, Cincinnati, Ohio: "Registratio Under the Canada Medical Practice Act," by Dr. W. Powel Registrar of the Medical Council of Canada, Ottawa, Ont. Ther will also be papers dealing with the subject of medical licensur in the United States by well-known speakers. Among thos who have agreed to join in the discussions are: Dr. Victor C Vaughan, president-elect of the American Medical Association, Ann Arbor, Mich.; Dr. John L. Heffron, dean of Syracuse University College of Medicine, Syracuse, N. Y.; D Walter L. Bierring, president of the Iowa State Board o Medical Examiners, and others. On the day following the conference of the Council on Medical Education will be held th annual meetings of the Federation of State Medical Boards o the United States and of the Association of American Medica Colleges. There is every promise that this series of conferences will be both interesting and helpful.

The Small-Pox Situation.—Small-pox has been more prevalent throughout the United States during the present fal and winter than for a number of years. Without making an attempt to gather accurate statistics concerning the diseas it is interesting to note that it has been reported durin January from about 225 cities and towns, the cases rangin in number from a few cases to a hundred or more in one place In many places the schools have been closed, and in other not only the schools, but churches and places of public amusement. Business has also been interefered with. Vaccinatio has been urged everywhere and has been made compulsory i many places under state or local laws and ordinances, an quarantine with its annoyance, loss of time and enormou expense in proportion to the good it accomplishes, has bee enforced. Opposition, organized and otherwise, has arisen i a number of places against the efforts of the authorities t quickly stamp out the disease. The anti-vaccinationists, blind to all the evidence as to the efficacy of vaccination, may always be counted on to make as loud a noise as possible, where prompt and vigorous action is especially necessary to control the disease.

The small city of Niagara Falls, which is spoken of as an "antivaccination center," has had about two hundred cases, with as many as 79 houses under quarantine at one time. The opposition to the efforts of the local health officer to secure thorough vaccination and carry out other measures for the eradication of the disease led to a protest to the state authorities by the city health officer of the neighboring city of Buffalo. An expert was sent to Niagara Falls by the state board to cooperate with the local authorities.

Toledo, Ohio, also had a large number of cases during December and January. An order by the local health board that the schools be kept closed early in January and that all teachers and children must be vaccinated or show a certificate as to a successful vaccination before entering the reopened schools on January 5, was ignored by the schoolboard and the schools were reopened, but later closed again. The spread of the disease, however, led to another order by the health board January 15 which made vaccination compulsory not only in the schools but in business and industrial establishments, under penalty of quarantine and a demand on the city councils for an appropriation of $25,000 to fight the disease. The surrounding cities of Ohio and Michigan addressed inquiries to the authorities of Toledo as to what was being done to fight the disease effectively, and intimated that quarantine might be declared against the city. Notwithstanding all this the antivaccinationists under the celebrated name of the League for Medical Freedom organized to oppose the efforts to get rid of the disease, and even went so far as to file charges and demand the removal of the city health officer for attempting under the laws of Ohio and according to established scientific methods to protect the people of Toledo against this loathsome disease. The correct methods prevailed, of course, and the disease will soon be under control.

In San Diego similar opposition and conflict of authority between the health department and the school board created a regrettable situation for a time.

In Iowa the ignorance or carelessness of some physicians in diagnosing cases as chicken-pox which afterward turned out to be small-pox, with consequent spread of the more serious disease, led to an order by the state board that all cases of "chicken-pox" as well as small-pox be quarantined. This aroused a good deal of opposition, but is believed to have been justified by the state board. In many places an attitude is assumed by the people and the authorities, and sometimes, though not frequently, by the health officer, which results in imperfect protection or the continuation and increase of cases. It is illustrated by the recent action in Keokuk when there were reported to be twenty cases of small-pox in the city. The city health board reported the situation as serious and demanded vaccination, but after a conference with the school and city authorities it was reported as "the consensus of opinion that compulsory vaccination was not imperative at this time. Should conditions change and grow worse it will be ordered" The mayor and the commissioner of public safety, it is said, did not consider the situation serious, though the health officer and the president of the school board, also a physician, believed it to be serious

Small pox when present is always serious, and the plan of waiting until an epidemic difficult to handle has arrived before adopting preventive measures is an absurdity that is perpetrated in numerous places Vaccinate first and then the disease will not appear Immunity gained by having the disease is a highly disagreeable and expensive, not to say dangerous method, but the wide spread presence of the disease this winter proves that this is the method by which many communities are acquiring it

FOREIGN

Profit from State Monopoly of Quinin in Italy.—It is stated that the net profits for the fiscal year 1911 1912 were 919,723 lire, an increase of 76,000 lire over the year before This net profit of nearly $200,000 has been added to the fund for combating the causes of malaria

Carnegie Hero Medal Awarded to Physician in Italy—One of the Carnegie hero medals and $200 were presented recently to Dr P Foianini of Grosio on account of his having sucked a diphtheric membrane from the throat of a woman on whom he was doing a tracheotomy and who was *on the point of* suffocating The woman was saved, but the physician developed the disease himself in a severe form

Annual Meeting of the German Surgical Association—Professor Muller of Rostock is to preside at the Forty Third Annual Meeting of the German Gesellschaft fur Chirurgie, which is to be held at Berlin, April 15 to 18 The subjects appointed for discussion are the "Ultimate Outcome of Transplantation of Thyroid Tissue," to be introduced by Kocher of Bern, "Postoperative Abdominal Hernia," by Sprengel of Brunswick, and "Bladder Tumors," by Hildebrand and Joseph of Berlin

Prize for Work on Microbiology.—It is announced from Copenhagen that the E C Hansen prize is to be awarded this year for the first time The date is May 8, and the prize consists of a gold medal and a sum of at least 2,000 crowns It is to be given to the author of some prominent work on microbiology which has been published in Denmark or elsewhere in the course of recent years, dealing with the morphology and mode of action of microbes pathogenic for man and beast Besides the four Danish members of the committee of award, it includes Profs Theobald Smith of Boston, Gaffky of Berlin and Calmette of Lille For further details address the chairman of the committee, Prof S P. L Sørensen, Carlsberg Laboratoriet, Copenhagen, Denmark

CANADA

Good Work in Diphtheria—In the past two years the Toronto Isolation Hospital has invested in diphtheria antitoxin $9,000, or more than in similar periods in former years The result has been the saving of fifty lives

Reorganization of Medical Department.—The western medical system of the Canadian Pacific Railway is being completely reorganized The operation of the medical services will be in the hands of an executive committee who will appoint all the medical men and draw up regulations governing the service

Communicable Diseases—All the public schools in Ingersoll, Ont, have been closed owing to an epidemic of diphtheria ——A rigid quarantine against small pox in Niagara Falls, N Y, has been established in Niagara Falls, Ont The director general of Public Health, Ottawa, has appointed Drs Horace R Elliott and Frank W E Wilson quarantine officers to regulate the passenger traffic over the border All persons entering Canada who cannot show certificates or proofs of vaccination within seven years will be rejected

Hospital News—The Toronto General Hospital funds have passed the $3,500,000 mark, and the entire amount has been raised with the exception of $85,000 The total number of inmates is 1,080——Calgary, Alta, is planning to build a $30 000 tuberculosis hospital——The Board of Trade, Perdue, Sask, recommends that a hospital be established in that town——The Tranquille (B C) Sanatorium for Tuberculosis has to face a deficit of $15,000 for its operations for 1913 With the addition of the proposed new buildings to cost $100 000, on the same basis of administration, the deficit would amount to double that amount in 1914 Detailed statements showing the necessity for additional governmental assistance have been placed before the British Columbia Government, who are being asked to make an increased grant for maintenance and to provide the funds for the erection of the new building

LONDON LETTER

(From Our Regular Correspondent)

London, Jan 24, 1914

A New View on Vaccination

Dr. C. K Millard, health officer of Leicester, delivered the first of the three "Chadwick Public Lectures" on "The Vaccination Question in the Light of Modern Experience" The lecture was remarkable in that an entirely new position intermediate between that of the antivaccinationists and the orthodox view was adopted by an authority on public health In this country professional opinion has always been almost unanimously in favor of vaccination, but there has been a sprinkling of eminent physicians such as Dr Creighton and Sir William Collins, M D, F R C S, K C V.O, opposed to it The latter, who presided at this lecture, is chairman of the Chadwick trustees, and the fact that he was a very active member of the royal commission on vaccination and largely responsible for the minority report of the commission, while the lecturer is the chief public health official for the town of Leicester—so long regarded as the Mecca of the antivaccinationists—gave the lecture a special interest

Dr Millard explained his personal position in regard to vaccination When he first went to Leicester his views on the subject were strictly orthodox, but in consequence of his experience with small pox in Leicester and of the close study of the question he has been obliged to modify those views considerably He is a thorough believer in the power of vaccination to protect the individual temporarily On the other hand, he has become skeptical as to the value of vaccination to the community at the present day He attributed the bitterness felt by the opponents of vaccination to the compulsory clauses of the vaccination acts and the tyranny with which these had often been enforced There was also the repulsion which many persons undoubtedly felt to the introduction of a disease into a healthy child for the sake of preventing another disease, the risk of contracting which he considered problematic It would ultimately be discovered that the whole truth about vaccination would not be found on either one side or the other, but that both sides were partly right and partly wrong The question of vaccination was not nearly so simple as many people appeared to think.

His own views are as follows

1 I believe absolutely in vaccination, though with certain important reservations, and I differ *in toto* from the anti vaccinationist when he asserts that vaccination is a "myth" and a "delusion" I agree entirely with the provaccinationist that recent vaccination confers on the individual protection against small pox which for practical purposes is complete, though unfortunately only temporary

2 Vaccination, repeated as often as necessary is invaluable for protecting those who for any reason are specially exposed to the infection of small pox, as doctors and nurses

3 It is also of very great value for protecting persons after actual exposure to infection, as small pox contacts

4 Vaccination has a remarkable power of modifying and mitigating small pox for many years after its power to protect against attack has worn out Moreover, the protection conferred by vaccination can be renewed by revaccination

5 On the other hand I agree with the antivaccinationist in doubting the value to the community, at the present day, of infantile vaccination An exaggerated view has been taken as to the effect of such vaccination in preventing the spread of small pox, which is the real problem before us

6 I agree with the antivaccinationist that sanitation, notification isolation, surveillance of contacts, and other modern measures which are becoming generally adopted have played a more important part in the abolition of small pox from this country during the past thirty or forty years than infantile vaccination

7 I think the antivaccinationist is right when he contends that the drawbacks to infantile vaccination, and the injuries to health caused by it are not sufficiently recognized by the medical profession, who, in their sincere anxiety to defend vaccination, have been inclined to minimize these drawbacks

8 On the other har [illegible] in his hostility to vaccination has grossl [illegible] backs while endeavoring to prejudice the [illegible] making wild assertions about the nature and origin of vaccine lymph, etc

9 There is distinct evidence that small pox is leaving this country in spite of the increasing neglect of vaccination, and it seems probable that such neglect of vaccination will continue to increase until the great majority of the population has become unvaccinated I am inclined to believe that when this happens the problem of small pox prevention will very possibly be simplified and made more easy rather than more difficult

10 The great difficulty in controlling the spread of small pox at the present day is the occurrence of very mild unrecognized cases which spread infection broadcast before precautions can be taken They occur almost entirely among vaccinated persons and *because they were so vaccinated* In other words, infantile vaccination, by its very success in mitigating small pox after its power to protect from attack has worn out, may have a distinct tendency to encourage the spread of the disease It is possible that this tendency more than neutralizes any benefit which the community derives from the fact that vaccination largely protects the child population from small pox

Dr Millard considered that the *antivaccinationists made a* great mistake in contesting the protective influence of vaccination on the individual, as this had been abundantly proved beyond all doubt. The real question now was: What is the protective influence of vaccination on the community? He showed a number of diagrams illustrating the fall in small-pox mortality and proving that this was specially marked since the "era of sanitation," during which such measures as notification and isolation had come into operation. Diagrams showing that although the proportion of infants vaccinated had been declining the small-pox mortality had been undergoing the same change were also produced. He considered that the universal vaccination of the community was therefore much less important than had been supposed.

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Jan. 17, 1914.

The Struggle with the Krankenkassen

No important progress has been made in the negotiations for an agreement with the Krankenkassen during the past week. To be sure, the Stettin Krankenkassen, after long negotiations, expressed themselves as ready to carry out the conditions agreed on, but in Breslau the insurance societies are objecting to compliance with the chief demand, that is, the dismissal of the emergency men already appointed, the so-called "strike-breakers." Compliance with this demand, however, is regarded by the Leipsic League as a prerequisite to the final settlement of the difficulties. As a result, the confidential advisers of the Leipsic League met again in Leipsic on the 11th and passed the following resolutions:

> After the German medical profession promptly and without reserve ratified the agreement of December 23, the advisers and authorities of the Leipsic League, assembled at Leipsic, Jan. 11, 1914, learned with great surprise that the termination of the conflict has not yet been secured in several places, for instance, Brunswick, Breslau and Elving, by the immediate discharge of the medical emergency men, according to the eleventh section of the agreement. They regard the performance of the conditions of this section as an unconditional prerequisite for the fulfilment of the agreement, and are of the opinion that if these conditions are not promptly complied with, the validity of all the contracts that have so far been made on the basis of the agreement will be placed in doubt, and an important reason for their immediate abrogation will be afforded. The advisory board would most deeply regret that the physicians should be compelled to renew the struggle for this reason.

I have no doubt that the few rebellious insurance authorities will yield, for the government has finally recognized the true significance of and justification for the demands of the medical profession, and will spare no pains to break the opposition of the insurance societies.

Increase in the Excess of Births in Prussia

The latest statistics show that there is a slight increase in the excess of births over deaths in Prussia. The figures indicate, however, that calculated per thousand inhabitants the reduction in the birth-rate has not yet ceased. The diminution in the number of marriages is also notable. In the cities this reduction is evidently connected with the unfavorable economic conditions.

The Charlottenburg Housing Office

On account of the great importance of housing conditions for public health and social conditions, a number of large cities have of late devoted great attention to the organization of supervision of dwellings and have created institutions for the purpose of carrying out such control of the housing conditions. Thus, housing bureaus have been established in Berlin as well as in Charlottenburg. A member of the Charlottenburg administration has lately reported his experience in the work of the Charlottenburg Housing Bureau during the first two years of its existence. This report will attract general interest. The theoretical foundation for the work of this bureau is first a housing survey, which determines how the poorer classes of the population live, especially how the lodging-houses and the accommodations for servants are constructed, as this style of living is the source of harm in regard to culture, morals and health. By systematic determination of these evils a housing reform will be prepared for. The removal of the present defects is a second theoretical basis for the Housing Bureau, which included the care of dwellings, and is an interference with the private rights of individuals, which demands therefore strict rules that will prevent any arbitrary proceedings. It is not through police regulations but by the establishment of minimum requirements as to the condition of the house, the separation of the sexes and the relation of landlord and renter that this aim ought to be reached. A cooperation of regular officers and voluntary helpers and the employment of women have been of great service in the Charlottenburg organization. There are three house inspectors who have had a technical education and one full time visitor who has had an education in sociology and is employed in caring for the social conditions. The inspectors examine the dwelling and indicate on the house cards the way in which the defects which are found should be remedied. When extensive changes are requisite, their institution is determined by the housing committee, of which there are fourteen, each consisting of four persons, one a city physician (poor physician). Superior to these committees is the deputation for housing affairs, which decides questions involving general principles and promotes such positive measures as the assistance of popular building-societies, the erection of homes for single people, etc. To this deputation a large number of expert citizens, including three women, belong. Each citizen delegate is also a member of a housing committee. Those matters which cannot be settled here are referred to the police as the last resort. The assistance of the police is immediately requisite only for the control of the lodging-houses. Connected with the housing bureau is a register of dwellings where all dwellings must be registered. This registration is free. In the first two years of the work of the housing bureau 557 houses were inspected, in which 1,171 defects were found and were charged to the owner. In 5,400 flats (only apartments of two rooms and a kitchen were inspected, of which there are 40,000) there were found 2,400 defects which were caused by the renter. The defects consisted especially of failure to separate the sexes, unauthorized introduction of lodgers and a lack of beds. A seventh of all the water-closets served for more than two families; 209 corridors and dark chambers were used as sleeping-rooms; 140 apartments were completely, and 1,702 partly overcrowded, if the standard of 4 square yards (4 square meters) of floor-area for each person is adopted. Of 2,000 such defects only 259 have not yet been remedied in the second year. Of 89 cases of overcrowding the first year, there were only 14 not remedied by the end of the second year. Thirty-seven cases were settled by transfer to other apartments with the help of the apartment register. Ten flats were voluntarily closed on account of insanitary conditions, and 57 water-closets were constructed without help of the police. There were 866 bedrooms used by lodgers in common with members of the family, and in 1,389 cases the use of the kitchen by lodgers was permitted.

Marriages

Frederick D. Cartwright, M.D., Bowling Green, Ky., to Miss Mayme Mitchell of Glasgow, Ky., at Louisville, January 15.

Arthur Moses Greenwood, M.D., Marblehead, Mass., to Mrs. Josephine Lyons Pemberton of New York City, January 17.

Chauncey Walter Strauss, M.D., Copperhill, Tenn., to Miss Dorothy G. Beyland of Newport, Ky., Nov. 27, 1913.

Harry Leslie Langnecker, M.D., to Miss Josephine Roome Macdonald, both of Cambridge, Mass., January 28.

DeWitt Carter Adams, M.D., Detroit, to Miss Helen Brownlee Brooks of St. Louis, at Detroit, January 21.

Thomas Grover Orr, M.D., North Bennington, Vt., to Miss Helen Harris of Syracuse, N. Y., Dec. 22, 1913.

John Lee Riley, M.D., Henryetta, Okla., to Miss Frances Lamping of Little Rock, Ark., Dec. 11, 1913.

Clarence Arthur Read, M.D., to Miss Elizabeth Bosworth, both of New Rochelle, N. Y., January 15.

Charles McClure, M.D., Cox's Creek, Ky., to Miss Mary Ellen Lisco of Bardstown, Ky., January 29.

Nina Leola Allen, M.D., San Diego, Cal., and William E. Gird of Bonsall, Cal., January 14.

Frank Homer Kennedy, M.D., to Miss Nellie Youngs, both of Greenwood, Wis., January 14.

Frederick James Port, M.D., to Miss Gretchen Blaser, both of Milbank, S. Dak., January 28.

William C. Wessel, M.D., to Miss Anna Roethemeier, both of Hermann, Mo., January 18.

Mark Hornstein, M.D., to Miss Henrietta Offerman, both of New York City, Dec. 21, 1913.

William Barton Skelton, M.D., to Miss Edna Dunstan of Dollar Bay, Mich., January 6.

Cleveland H. Shutt, M.D., to Miss Alice Bock, both of St. Louis, January 22.

Deaths

Brigadier-General Alfred C. Girard, U S Army, retired; died at his h[illegible] D C, January 31, after an operation for [illegible] He was born in Switzerland, July 31, 1841, was graduated from the University of Wurzburg, Germany, in 1864, and entered the United States Army as acting assistant surgeon, Jan 19, 1865 In 1867 he was made assistant surgeon U S Army, and after passing through the various grades was retired as brigadier general at his own request, April 7, 1905 During his service he passed through several Indian campaigns and acted as chief surgeon of the Second Army Corps during the Spanish American War After his retirement he resided in Chicago, and was librarian of the medical department of the John Crerar Library until 1911, when he moved to Washington General Girard was a Fellow of the American Medical Association and a member of the Association of Military Surgeons of the United States and was at one time Medical Director of the Department of Idaho of the Grand Army of the Republic

Andrew Flint Sheldon, M D New York University, New York City, 1852; assistant surgeon of the Seventh New York Volunteer Cavalry, and Seventy Eighth New York Volunteer Infantry, later executive officer in the medical director's office, Washington, commissioned major and surgeon of United States Volunteers, and placed in charge of the Campbell United States General Hospital, Washington, and brevetted lieutenant colonel for meritorious services during the Civil War, treasurer of Wayne County, N Y., for three years, died at his home in Lyons January 24, aged 83

Gustave R. Feil, M D University of Wooster, Cleveland, Ohio, 1891, a member of the Colorado State Medical Society, visiting physician to the National Jewish Hospital for Consumptives and Mercy Hospital, Denver, died at his home in Denver, January 16, from the effects of a gunshot wound of the head, self inflicted, it is believed, with suicidal intent, while despondent on account of ill health, aged 42

Stephen L Powlett, M D. (license, Louisiana) a practitioner for forty three years, ambassador from the United States to Guatemala during Cleveland's administration, later a practitioner of New Orleans and Hammond, La, and mayor of the latter city, at one time colonel on the staff of Governor Sanders and surgeon general of the National Guard of Louisiana, died at his home in Hammond, January 7

George C. Losey, M D Northwestern Medical College, St Joseph, Mo, 1888, a member of the Missouri State Medical Association and a practitioner of Almon, died Dec 2, 1913, from the effects of an accident which occurred while he was returning from a meeting of the Hickory County Medical Society

A Carl F. Reinhard, M D. University of Marburg, Germany, 1870, a Fellow of the American Medical Association, surgeon in the Prussian service during the Franco German war, and for a time a surgeon on transatlantic steamers, a practitioner of Milwaukee since 1876, died at his home January 12, aged 66

Alonzo F Huntoon, M D Missouri Medical College, St Louis, 1881, formerly a Fellow of the American Medical Association, a member of the Medical Society of the State of California, died at his home in Los Angeles January 13

Philip Benton Spears, M D Georgia College of Eclectic Medicine and Surgery, Atlanta, 1891, a member of the Medical Association of the State of Alabama, died at his home in Florala, January 12, from heart disease, aged 61

James J. Richardson, M D University of Louisville, Ky, 1866, a Confederate veteran, for many years head physician of the Cumberland Sanatorium Lebanon, Tenn, died in that place, January 8, from bronchial asthma, aged 73

Curtis William Otwell, M D Columbus (Ohio) Medical College, 1876, a veteran of the Civil War, in which he served as an assistant surgeon, died at his home in Independence, Kan, January 8 from senile debility, aged 76

Joseph Bailey Thomas, M D University of Iowa, Iowa City, 1883 for thirty years a practitioner of Carthage, Mo, died in the Touro Infirmary, New Orleans, January 7 three days after an operation for gastric ulcer, aged 54.

John V. Webster, M D Cincinnati College of Medicine and Surgery, 1870, of Flushing, Ohio, died in the Columbus State Hospital, January 6 from tuberculosis aged 66

James Roy McIntire, M D. Southwestern Homeopathic Medical College, Louisville 1902; died at his home in Carlisle, Ky, January 9, aged 32

Edward Warren King, M.D. Cooper Medical College, San Francisco, 1863, from 1892 to 1912, superintendent of the Talmage (Cal) State Hospital, died at his home in San Francisco, January 11, aged 82

Joseph W. Newcomer, M.D. Jefferson Medical College, 1864; a member of the Illinois State Medical Society; for forty-eight years a practitioner of Petersburg; died at his home in that city, January 14, aged 75

John Washington Farill, (license, Cherokee County, Ala, 1887) a member of the Medical Association of the State of Alabama, died at his home in Farill, Dec 15, 1913, from senile debility, aged 83

Robert C. Young, M D. McGill University, Montreal, 1873, from 1874 to 1911 a practitioner of Ridgetown, Ont, and since that time a resident of Detroit, died at his home Nov 25, 1913, aged 63

James A. Sexton, M D University of Maryland, Baltimore, 1873, a Confederate veteran and later register of deeds of Harnett County, N C, died at his home in Harnett, January 7, aged 69

John S Whatley, M D. Tulane University, New Orleans, 1880, a director of the First State Bank of Chillicothe, Tex; died at his home in Chillicothe, January 12, from pneumonia, aged 59

Charles Orendorff, M D. University of Pennsylvania, Philadelphia, 1862, for fifteen years a resident of Colony, Kan, died at his home in Yates City, Kan, Dec 26, 1913, aged 81

Alfred Huntington Ketchum, M D. University of Alabama, Mobile, 1871, since 1873 a practitioner of Texas, died at his home in Navasota, December 24, aged 66

Mary J. McCleery, M D. Woman's Medical College of New York Infirmary, 1877, died at her home in New York City, January 12, from heart disease, aged 70

Thomas Osgood Reynolds, M D Albany (N Y.) Medical College, 1866, a veteran of the Civil War, died at his home in Kingston, N H, Dec 12, 1913, aged 71

August Wilhelm (license, California, 1876); a practitioner for fifty three years, died at his home in San Francisco, January 6, from arteriosclerosis, aged 80

Isaac B Loos, M D. Jefferson Medical College, 1888, a Fellow of the American Medical Association, died at his home in Trenton N J, January 13, aged 50

Henry P. Howard, M D. Columbian University, Washington, D C, 1851; died at his home in Dallas, Tex, November 21, aged 82

Max Dantes, M D. Bellevue Hospital Medical College, 1893; died at his home in New York City, January 7, aged 41

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory, Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

SAL HEPATICA

Report of the Council on Pharmacy and Chemistry

Sal Hepatica, marketed by the Bristol Myers Co of New York, has been refused recognition by the Council, because its composition is secret, because it is advertised indirectly to the public for the treatment of diseases, because exaggerated and unwarranted claims are made for its therapeutic qualities, and because the name fails to indicate its chief constituents but does suggest its use in liver disorders

The Council has authorized the publication of the report of its referee, because it is an important illustration of the ways in which physicians are being made parties to the introduction to the public of a patent medicine, whose indiscriminate use must often have resulted in harm, direct or indirect

W A Puckner, Secretary

The report of the referee follows

Sal Hepatica is a saline laxative sold by the Bristol Myers Company of New York No information seems to be given regarding its composition except such as is contained in the following vague and uninforming phrases

"Effervescent saline combination, hepatic stimulant, laxative and an eliminant of irritating toxins"

"Sal Hepatica is a saline combination containing the alterative and laxative properties similar to the natural 'Bitter Waters' of Europe with the addition of sodium phosphate "

" more palatable and efficient than sodium phosphate alone or other salines"

A circular around the bottle contains the following

"We invite the physicians' careful consideration of the merits of Sal Hepatica in the treatment of Rheumatism and Gout, in Constipation and Auto intoxication, and to its highly important property of cleansing the entire alimentary tract, thereby eliminating and preventing the absorption of irritating toxins and relieving the conditions arising from indiscretion in eating and drinking"

In the same circular, its promiscuous use is invited in these terms

"Owing to its palatability, Sal Hepatica is particularly well adapted to the requirements of childhood or the feeble and delicate"

Further suggesting its use in the treatment of that popular, if somewhat vague ailment, "biliousness," we read

"It is especially valuable where there is intestinal sluggishness arising from functional derangements of the liver or portal circulation "

As further suggestive of its all around "goodness," are the claims

"It increases the appetite and promotes digestion by stimulating the flow of gastric juice"

"In rheumatism and gout Sal Hepatica furnishes the physician with an ideal eliminant, usually affording prompt relief"

The label on the Sal Hepatica bottle suggests—both to physicians and the public—its use in the following diseases and conditions

"Derangements of the stomach and liver"
"Affections of the kidneys"
"Bilious attacks"
"'Summer complaints' colic and alcoholic excesses"
"Headache dizziness, heartburn and seasickness
"Acute indigestion
"Gastric hepatic and renal disorders
"Especially beneficial in rheumatism and gout"

From these quotations it is evident that Sal Hepatica is in conflict with

Rule 1, in that its composition is not disclosed, although statements are made which are likely to give a false impression as to what it is;

Rule 4, in that the statements on the label and in the circular around the bottle advertise it to the public and thus makes the physician who recommends it an advance agent for the nostrum,

Rule 6, in that exaggerated and unwarranted claims are made for its therapeutic qualities, and,

Rule 8, in that its name fails to indicate its chief constituents but does suggest its use in liver disorders

The absurd claims made for this preparation are such as to put it in the "patent medicine" class Even the most credulous members of the medical profession certainly can take no stock in the claim that a preparation can be an "eliminant" of uric acid, a hepatic stimulant, a remedy for gout, rheumatism, liver disease, indigestion, etc, why then should such a preparation be tolerated!

In its conflict with Rule 4 Sal Hepatica belongs to that class of nostrums which have been so successfully exploited by manufacturers through the unwitting efforts of thoughtless and careless physicians The Bristol Myers Company has been most liberal in distributing free samples, evidently with the assurance that physicians would do the rest Thus, at the present time, the profession is being supplied with a package containing one regular 25 cent bottle and five single dose vials bearing the name Sal Hepatica If only a small percentage of the physicians who receive these samples distribute them, the increase in Sal Hepatica consumers may be imagined How successful this scheme of the Bristol Myers Company has been is only too evident Sal Hepatica is one of the best selling laxatives in department stores and drug stores to day

While the evils of indiscriminate purgation are now generally recognized, the referee wishes to quote and to indorse the pertinent comments on this subject by The Journal [1]

"The abuse of saline cathartics by the public is an evil deserving of serious attention Rightly or wrongly, the laity fear constipation and naturally take what they are taught to believe is the cheapest and simplest course for its relief, self drugging by means of saline cathartics or the extensively advertised purgative mineral waters This habit is responsible for much of the distressing spastic constipation that exists, and its accompanying neurasthenia The advertisement and sale to the laity of such a nostrum as "Sal Hepatica" can only increase these evil results and the physician who aids and abets the evil by using the preparation should reflect whether he is thereby not only encouraging a fraud on the public but also, what is even worse, helping to impair the public health"

It is recommended that this report be authorized for publication in order that physicians may know the extent to which they have been made to act as advance agents for "patent medicines" It is hoped its publication may suggest to those who in thoughtlessness have recommended Sal Hepatica, that they go to their materia medica and renew acquaintance with the host of simple and efficient laxative salts which are available—magnesium sulphate, sodium sulphate, sodium phosphate and the palatable effervescing preparations of these which the Pharmacopeia provides—effervescent magnesium sulphate (Magnesii Sulphas Effervescens, U S P), effervescent sodium phosphate (Sodii Phosphas Effervescens, U S P).

LIPPINCOTT'S MAGAZINE

Its Advertising—A Protest and An Excuse

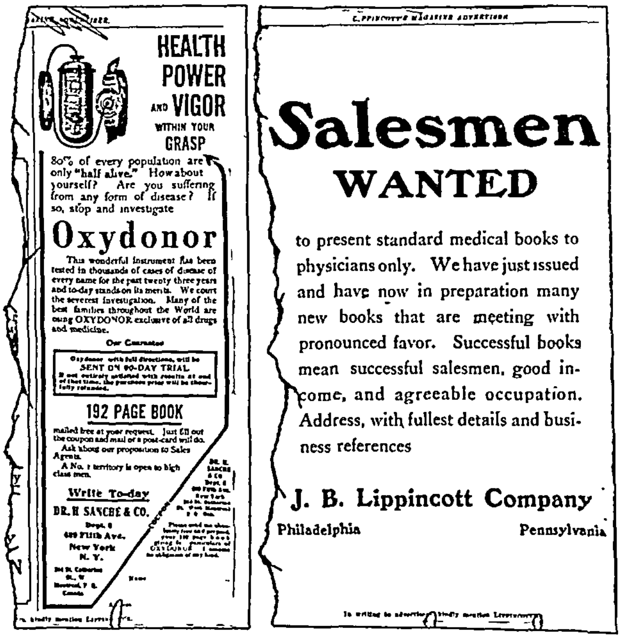
A few days ago a physician wrote to The Journal enclosing two advertisements taken from the current issue of *Lippincott's* magazine One of these was a half page advertisement of that outrageous fraud, the "Oxydonor", the other was a full page advertisement of J B Lippincott Company, Philadelphia, calling for salesmen "to present standard medical books to physicians only"

The physician sending in this material asked us to send to Lippincott's a pamphlet showing the fraudulence of the Oxydonor Instead of doing so we sent the pamphlet to the physician and suggested that he write a personal letter in the belief that individual missionary work is the most effective way of fighting fraud. Accordingly the doctor wrote to *Lippincott's* and received in reply this letter from the advertising department of that publication:

---

[1] The Journal A M A, March 26, 1910, p 1071

> "Your letter of the 23d received, and in reply beg to say that we do not approve of fraudulent advertising, and we have never before been advised that the advertisement to which you call our attention was objectionable. *In fact, we know nothing whatever about it.* [Italics ours.—ED.] It came to us, as do most of the others, through an advertising agency, and while we do not willingly publish anything that is fraudulent or objectionable, *it is not our custom to verify the claims of advertisers,* [Italics, again, ours.—ED.] especially when the same copy is being run in almost every other high-grade publication.
>
> "We have a very high regard for the American Medical Association, and they undoubtedly are doing a splendid work in ridding the country of fake medical preparations, but the mere fact that they condemn some one of our advertisers is hardly sufficient proof for us to refuse the advertising, because, *if the advertiser desires to do so, he can make us prove in the courts that he is a faker, or claim damages from us for refusing to publish his advertisement.* [Our italics.—ED.]. If the American Medical Association will guarantee to protect the publishers against loss from damage suits brought by advertisers whose business they refuse to accept, then, we believe that the publishers would gladly reject them, but not many of the publishers are in a position to investigate the merits of all the advertising that is offered, especially when the claims are backed up by affidavits of reputable people who believe themselves to have been cured by the preparation.



HEALTH POWER AND VIGOR WITHIN YOUR GRASP

80% of every population are only "half alive." How about yourself? Are you suffering from any form of disease? If so, stop and investigate

Oxydonor

This wonderful instrument has been tested in thousands of cases of disease of every name for the past twenty three years and to-day stands on its merits. We court the severest investigation. Many of the best families throughout the World are using OXYDONOR exclusive of all drugs and medicine.

Our Guarantee

Oxydonor with full directions, will be SENT ON 90-DAY TRIAL.

Salesmen WANTED

to present standard medical books to physicians only. We have just issued and have now in preparation many new books that are meeting with pronounced favor. Successful books mean successful salesmen, good income, and agreeable occupation. Address, with fullest details and business references

J. B. Lippincott Company
Philadelphia Pennsylvania

Photographic reproduction (much reduced) of two advertisements from January, 1914, *Lippincott.* One of a fraudulent quasi-medical device, the "Oxydonor"; the other, calling for salesmen to introduce "standard medical books to physicians."

> "We certainly do not wish to jeopardize our medical publications by advertising fake schemes or propositions of any kind, and we thank you for writing us concerning the matter and will now look into this particular case."

This letter discloses the workings of the brain of an advertising man of the old school. The principles enunciated therein are those that dominated the advertising field until quite recently. They represent the *laissez faire* doctrine as applied to advertising. At that time the only unacceptable advertising copy was that which would debar the publication using it, from the United States mails. This was the yardstick by which all advertising was measured—at that time.

The economic conscience has since awakened. There are few reputable magazines to-day, we venture to believe, that would be willing to go on record to the effect that it is not their "custom to verify the claims of advertisers." The modern, progressive advertising man recognizes not only the responsibilities his profession imposes, but also realizes that, from the narrower view of enlightened self-interest, the greatest menace to the future of modern advertising is the fraudulent advertisement.

The claims on the part of the advertising department of *Lippincott's* that it dares not refuse to accept fraudulent advertisements because the advertiser might bring suit against it for refusing to accept his advertisement, is a statement whose falsity is exceeded only by its silliness. Equally preposterous is the statement that *Lippincott's* will willingly refuse to accept fraudulent advertisements provided the American Medical Association will guarantee to protect the Lippincott Company against loss from damage suits that may be brought by the exploiters of the frauds whose advertisements are refused.

It may be news to *Lippincott's* to learn that there are a score and more of newspapers and magazines that are accepting the findings of the American Medical Association on medical frauds and rejecting advertisements of such frauds. There are many newspapers that send us the medical advertising "copy" submitted to them and ask for an opinion on it. When that opinion is unfavorable, these papers refuse such advertisements. This is being done daily. We have yet to hear of any "patent medicine" faker or quack even threatening to bring suit because his advertisements have been rejected.

The advertising department of *Lippincott's* may therefore take heart. When an advertisement of an outrageous fake like the Oxydonor is submitted to it, instead of accepting the money for it, meantime muttering an inaudible protest at the unfortunate position in which it has been placed, it may look the fraud in the eye and say Boo! The faker will not bite.

Before leaving the subject, we are constrained to refer to Lippincott's medical publication, the *Annals of Surgery.* We begin to realize now why that journal offers a welcome haven to such products as Sal Hepatica, Bromidia, Papine, Gray's Glycerin Tonic, Fellow's Syrup of Hypophosphites, et al. Presumably the same "custom" obtains in the acceptance of advertising for the *Annals of Surgery* as for *Lippincott's*, namely that the Lippincott Company does "not verify the claims of advertisers." Possibly the *Annals of Surgery* is afraid that, should it reject the Sal Hepatica advertisement, for instance, it might be haled into court! Let us trust, for their peace of mind, that the publishers of the *Annals of Surgery* do not receive an advertisement from Old Doc Hartman for a full page display of Peruna. The mental anguish they would undergo in reluctantly accepting this advertisement—under the fear that Hartman would "claim damages" if it were rejected—is painful to contemplate.

ORRIN ROBERTSON

A Quack and His Seven Sacred Oils

The following interesting letter is from a lady living in one of the southwestern states:

> "Under separate cover I am sending you a copy of a preposterous circular sent out by one Orrin Robertson of Arkansas City, Kan. This paper was given to me by a lady who is connected with me by marriage and who has a cancer in what must be both an inoperative and incurable stage. Instead of going, as I begged her to, to one of the surgeons of M——— when there was only a small lump in her breast, she went first to Johnson of Kansas City, Mo., then to Weltmer of Nevada and now she is planning to go to Robertson.
>
> "It takes her hours every day to wash and cleanse the breast. It bleeds very freely, and has a raw open surface several inches in diameter.
>
> "How any one can take any stock in a man who can publish such a thing is unaccountable to me.
>
> "My doctor advised me to send the publication to you to have Robertson exposed in THE JOURNAL, as you are doing with other charlatans and frauds. You may say that he is not worth noticing, but he reaches *a great many people* who ought to know better, and his bitter denunciation of regular

practitioners and his 'proofs' of the awful things they give as medicines ('glandeine' for instance) are enough to shake the confidence of a very large class of people in the medical profession

"I have no hope of doing any good in the case I write of But an exposé in The Journal might help reputable physicians to keep others from taking the chances of going to him"

The preposterous circular that our correspondent forwards is a twenty eight page advertising sheet called *Robertson's Journal of Anthropology* Robertson calls himself "the Old Reliable Specialist, Discoverer, Originator and Founder of Anthropology, the Pneumo Psycho Manas Soma System" He has been quacking it for many years He was graduated in 1895 by the homeopathic department of the State University of Iowa, but five years before this he seems to have been at San Antonio, Tex His name does not appear again in the medical directories until 1900, at which time he is found at Louisburg, Kan From 1902 to 1908 he was at Quenemo, Kan, where he operated a fake institution known as the "American University of Anthropology" In 1910 he is found at Kansas City, Mo In 1911 he seems to have been at Agra, Okla At present writing he is at Arkansas City, Kan

Robertson claims to be a "graduate of thirty one different colleges, universities and institutions in this country and Europe" Some of the "institutions" from which he holds diplomas or certificates are

> *Society Oriental Mystics,* Chicago, Ill —N E Wood A M M D, president, Thomas J Betiero, M D, secretary, George V Booker treasurer
>
> *The Temple of Moomntaj Lyumbia "Ka Lama Zurija" India,* Chicago Ill Dr L W de Laurence Yoghee and High Caste Adept in Art Magic and Famous Magician of Alchemy and Fire
>
> *Ancient Order of Oriental Mystics,* Chicago Ill Andrew Black Ph D, president, T J Betiero, M D, secretary, E S Adams, treasurer
>
> *New York College of Magnetics* New York E D Babbitt M D dean, F G Welch, M D president board of trustees
>
> *New York Institute of Science* Rochester N Y La Motte Sage president, Thos F Adkins vice president J S Wharton, M D, secretary, Dutton Whitney, M D medical director
>
> *College of Therapeutics,* Boston Kansas City and Los Angeles Joseph Rhodes Buchanan, M D president

If anything further were needed to convince the thoughtful that Orin Robertson is a full fledged quack and fraud, his connections with these institutions should do it

There is nothing, apparently, that Robertson doesn't cure if one is to believe the balderdash he sends out in his *Journal of Anthropology* He particularly emphasizes his success in the "non surgical treatment of gall stones," a field of endeavor that seems to lend itself peculiarly to the quack and the charlatan The typical gall stone cure faker gives his victim a large dose of some bland oil, such as cotton seed oil or olive oil, follows it up by a saline cathartic and points with pride to the "gall stones," as he styles the soapy concretions that persons taking such a mixture pass

Robertson goes the old fake one better, he claims to remove gall stones by means of the "Seven Sacred Oils which grow in seven different climes" Not only this, but Robertson says "I never give the same oils to a person with light hair and eyes that I do to one with dark hair and eyes"

Robertson calls his "seven sacred oils" the "Elixir of Life" He claims

> "One oil acts specifically upon the entire head and throat
> "One oil acts directly upon the esophagus
> 'One oil acts directly upon the stomach

And so it goes, each oil acting a little lower down, until we reach the seventh oil which "acts directly" on the rectum More wonderful yet, we are told

> "In seven minutes after you take a dose of the seven oils rub your hand across the back of your neck and you can smell the oils
>
> 'In fourteen minutes rub your hand across the spine in the thoracic region and you can smell the oils
>
> "In twenty one minutes rub your hand across the spine in the lower dorsal region and you can smell the oils

And so on The figure seven is his Shibboleth Thus

> 'There are seven mineral substances and seven vegetable substances and seven mental substances and seven psychic substances and seven spiritual substances, which, when put together, doth mal a *Magical Compound,* which, when properly applied, according : the temperaments, subverts the diseases of the *Liver* It remov *Gall Stones*"

In addition to gall stones, Robertson also features a "cure for cancer Of course his treatment is "non surgical"—he do not cure by "cutting, burning, blistering or x ray" He ha the usual list of testimonials purporting to be from men an women who have been cured of cancer

To read the advertising matter sent out by Robertson an to realize that this hodgepodge of nonsense and charlatanr can and does deceive and defraud thousands of people, make one gasp at the depths of human credulity It causes th thoughtful to wonder whether the average intelligence in 191 is above that found in the days when magicians, witche gnomes and fairies were established institutions That suc fakers as Robertson are a real menace, however, is eviden from the facts brought out in the letter published above Th emphasizes the need of protecting the credulous sick an ignorant from the dangers to which their credulity and lac of knowledge expose them A state which throws the pro tection of an admirable "blue sky law" around the unsophisti cated investor should not tolerate for an instant such ' meanly fraudulent trade as that carried on by Robertson

MU-COL

Salt and Borax as Wonder-Workers

"Mu col, for Cleansing Mucous Membranes" is a nostrum pu on the market by the Mu col Company (Inc), Buffalo, New York As a specimen of the claims made for the preparation the following is typical

> Mu col obtains most gratifying results in catarrhal inflammations of the mucous membranes Leucorrhea, Tonsillitis Sore Throat, Cystitis Internal Hemorrhoids Nasal Catarrh and Pus Cases respond at once to irrigation with Mu col solution Strong solutions of Mu col have proven of sterling value in treating Hives, Prickly Heat, Ivy Poison, Sunburn, Eczema, Typhoid and Scarlet Fever'

This, and much more Mu col will do—according to its manufacturers! No wonder physicians want to know the composition of Mu col As the manufacturers do not give this information the aid of the Association's Laboratory was invoked Let the chemists speak

LABORATORY REPORT

"The specimen examined was a white powder, and from the odor, thymol, eucalyptol, camphor and oil of wintergreen could be recognized Qualitatively sodium, chloride and borate were found Zinc, benzoate, phenolsulphonate and sulphate could not be found The solution was alkaline to litmus Gravimetric determination of chlorid as silver chlorid and titration of borax by Thompson's method indicated sodium chlorid (NaCl) 47 2 per cent, sodium borate ($Na_2B_4O_7+10H_2O$) 50 1 per cent

"It thus appears that Mu col is a mixture of ordinary salt and borax in equal parts with the addition of a small amount of aromatic substances"

Mu col will do just what a solution of salt and borax will do—no more, no less And yet, it is claimed

> "Mu col has been successfully used since the year 1900 by more than 50 000 physicians which has proven it to be the most Efficient, Economical and acceptable preparation in its field

---

What Is a Scientific Attitude?—The attitude of science, to begin with that, is before all things a *disinterested* attitude witness the rise and growth of astronomy, of chemistry, of physiology Until mankind has learned to take experience in serious earnest "for its own sake," to subordinate personal ends to the pursuit of truth, there is no science but only something which at its worst is quackery and pseudoscience, at its best common sense and rule of thumb, and conversely, so soon as a man starts out to examine some aspect of experience as if it were for itself important and knowledge of it were intrinsically desirable, so soon does the germ of a science appear —Titchener in *Pop Sc Month*

Correspondence

Universal Circumcision as a Sanitary Measure

To the Editor.—I was much interested in the article on this subject (THE JOURNAL, Jan. 10, 1914, p. 92). I believe that there are many of us who do not fully agree with Dr. Wolbarst in his sweeping denunciation of non-circumcision. Obviously, this operation is indicated when phimosis exists, and the earlier the better. It is also indicated in elongated conditions of the prepuce, even if not constricted. Most excellent reasons have been advanced for the operation in such cases. But in the man whose foreskin is of such character as partly, or even wholly, to cover the glans when the penis is in a quiescent state, but automatically withdraws at the time of sexual excitement, I can see no valid reason for mutilating the penile organ. An exception might be made to this view of the matter in those who are neglectful of all laws of cleanliness and hygiene, but in this class circumcision is only one of a number of local attentions indicated, provided so extreme a method becomes necessary to keep such part of the person's anatomy clean.

For many years, in patients in whom the procedure is indicated, I have made use of a method which, to coin a name, might be termed a circumcisionoid—at least, so far as the desired results are concerned, for, of course, etymologically considered, the word is a false one—and that is to hold the prepuce back from the glans by action of a rubber band.

Such a fixture, of proper size and properly adjusted, just as fully and satisfactorily "circumcises" the individual as in case of its removal. I habitually make use of this procedure in all my venereal cases, and often as a means of sanitation. Still further, though I am unable wholly to account for the method of healing, I have observed the clearing up of long-standing cases of urethritis and prostatic irritation. In many cases, also, the presence of this band seems to train the parts in such a way as to make the prepuce hold its retracted position permanently, yet it is not lost to its owner.

The bands referred to are such as are ordinarily used as a substitute for twine in holding papers, small packages and the like. Care should be taken to select those having the greater width, in order to avoid injury to the delicate structures encircled.

JAMES BROWN THORNTON, M.D., Boston.

[The foregoing letter was referred to Dr. Wolbarst, who replied.]

To the Editor:—I believe in circumcision as a prophylactic measure; Dr. Thornton advocates the operation as a therapeutic measure. Conservatism is to be found in a wise prophylaxis which submits the infant to a slight and harmless operation, performed in a few seconds, rather than subject him to the serious risks which must be conceded to the possession of a foreskin. I admit that, in a man who is cleanly in his habits, a foreskin which moves freely over a clean glans, does not necessarily have to be removed. How do we know that any infant's foreskin is going to behave in this way when the child becomes a man? If we could foretell that, in adult life, such an infant will keep the glans and foreskin clean, that the prepuce will not be tight or long, that the man will not acquire venereal disease, or that he will not even subject himself to the risk of venereal infection, in such circumstances I should agree with Dr. Thornton that it would be just as well not to "mutilate the penile organ." But we do not and cannot know these things in advance, consequently, since I regard every foreskin as potentially capable of causing the pathologic conditions mentioned in my article, it seems best to take advantage of the accumulated experience of many centuries, and remove this useless bit of flesh, which can be of no possible service, and which we all agree, may do considerable harm.

As to the rubber band plan, two thoughts suggest themselves. The first is that it would be simpler and more efficacious to perform circumcision and be done with it, rather than compel the patient to wear the band all his life; secondly, that the wearing of such a rubber band, tight enough to retain the prepuce in place, might be conducive to a chronic hyperemia or congestion of the glans, which would in all probability give the wearer a sensation that would resemble a "permanent erection," of a mild degree. Dr. Thornton states that "the presence of this band seems to train the parts in such a way as to make the prepuce hold its retracted position permanently, yet it is not lost to its owner." Here we seem to have another argument for circumcision. Why should the prepuce be retracted permanently? And if it is well for the prepuce to be retracted permanently and thus expose the glans, of what good is it that "it is not lost to its owner"? If it does not serve its natural purpose of covering the glans, of what use is it to the individual, retracted back from the glans?

A. L. WOLBARST, M.D., New York.

Emetin Hydrochlorid in Amebic Dysentery

To the Editor:—In THE JOURNAL, Nov. 22, 1913, p. 1899, is reported a case of amebic dysentery treated with emetin hydrochlorid. This is the approved method of treatment for amebic dysentery among missionary physicians in China. In the *China Medical Journal*, March and July, 1913, are reported ten cases and seven cases, respectively, in which all the patients were treated with emetin hydrochlorid hypodermically and all were relieved of their dysenteric symptoms in an almost incredibly short time. In the former series, Case 5 did not respond so readily as the others, and it was not until the tenth day of treatment that the mucus disappeared from the stools. This was a case that had been treated unsuccessfully with ipecac powder six months previously. To me this is interesting, inasmuch as of the four cases I have had since Oct. 16, 1913, all of which were apparently cured with emetin hydrochlorid, the one case that did not respond readily had been treated with ipecac powder one year before. This patient came irregularly to the dispensary for eleven days, and received in six injections a total of 11 grains of emetin hydrochlorid. After the last injection of 2½ grains he was relieved of all symptoms. He showed no nausea or other discomfort as a result of the large dose. Is it not likely that in the two cases cited the previous treatment with ipecac influenced unfavorably the later treatment with the alkaloid?

JOHN H. KORNS, M.D., Tsinanfu, Shantung, China.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

"THE ANATOMIST" OF REMBRANDT

To the Editor:—I am enclosing a photograph of a picture that was a gift to me. I have forgotten the name of the picture and its history, and have been unsuccessful in finding the necessary information. Can you help me?

JOHN R. BLACK, M.D., Jefferson, Iowa.

ANSWER.—The so-called 'Lesson in Anatomy,' or more properly "The Anatomy of Dr. Tulp," was one of the first pictures painted by Rembrandt after he settled in Amsterdam in 1631. As he began to paint in Leyden in 1627 the data of this picture (1632) show it to have been also one of the earliest of his greater works. It hangs in the Hague Gallery. These dissecting scenes were favorite subjects of the Dutch and Flemish painters in the seventeenth century, and Rembrandt derived the idea from the earlier "Anatomies" of Pietersz (1603), Mierevelt (1617), de Keyser (1619) and Elias (1625) in the Amsterdam and Delft collections. The central figure of the picture is Dr. Nicolas Tulp (1593-1674) of Amsterdam who became reader of anatomy to the Surgeons' Guild in 1628, which office he held until 1653, after which he became burgomaster of Amsterdam (1654-1655, 1666, 1671). He described the ileocecal valve, discovered by Bauhin, but also called the valvula Tulpii, and, in 1639, was the first to demonstrate in man the lacteal vessels, which had been discovered by Aselli in the dog in 1622. He also compiled the first city pharmacopeia of Amsterdam (1636), through which the apothecaries were finally compelled to fill prescriptions in a uniform manner. In clinical medicine he made his mark by his description of beriberi (1652), in which he was preceded by Jacob Bontius (1642), the knowledge of this disease having of course been derived from the contact of the Dutch merchantmen with the East Indies. Two other facts go to make up his reputation as a "citizen of credit and renown," namely, that he was instrumental in making tea, which had also just come from the Far East, a household beverage, and that he was the first to describe an anthropoid ape, the chimpanzee, a fact which has been confirmed by Huxley. A fine portrait of Dr. Nicolas Tulp by Nicolas Elias hangs in the Six Gallery, Amsterdam. The names of the other physicians in the Rembrandt "Anatomy," from right to left, beginning with the lower row, are given as: Jakob Block, Jakob de Witt, Adriaen Slabraan, Jakob Koolveld, Hartmanez, Kalkoen and Franz van Loenen. The name of the dissected subject cannot be ascertained, as two dissections were made in Amsterdam during the year 1632. In 1656, Rembrandt painted one other great "Anatomy," that of Dr. Johan Deyman, which was partly destroyed by fire, Nov. 8, 1723, and now hangs, a fragment only, in the Amsterdam Gallery. It represents a dissection of the brain in a foreshortened cadaver, but the head of Deyman himself has been burned off, giving the appearance of a decapitated upright figure. When Sir Joshua Reynolds visited Holland in 1781, he was so much impressed with the execution and coloring of this picture that he said it reminded him of Michael Angelo and Titian. On account of its injury by fire, it was sold to a Mr. Chaplin of London in 1841, was exhibited at Leeds in 1868, and then disappeared, to be found long afterward by Geheimrat Bode, the Rembrandt expert, in the storeroom of the South Kensington Museum. It was then purchased by patriotic Dutch connoisseurs and taken back to Amsterdam.

The Anatomy of Dr. Tulp, by Rembrandt.

PONDER'S STAINING METHOD

To the Editor:—In the *United States Naval Medical Bulletin*, October, 1912, is described a new technic for staining diphtheria specimens with toluidin blue, as follows:

Toluidin blue (Grubler's)	0 02
Glacial acetic acid	1.
Absolute alcohol	2.
Distilled water to	100.

"The film is made in the usual way on a cover-glass and fixed by passing through the flame of a lamp. A small quantity of the stain is spread on the film, and the cover-glass is turned over and mounted as a hanging drop preparation. Typical diphtheria bacilli are said to stain blue with *red granules.*"

Will toluidin blue alone produce the double stain as described *above?* A. E. Conter, M.D., *Chattahoochee, Fla.*

Answer.—This query has reference to the method of Ponder, described in the *Lancet*, London, 1912, clxxxiii, 22. As is well known, the diphtheria bacilli are characterized by the appearance of metachromatic granules at their ends and throughout their protoplasm. These granules stain more deeply with the ordinary methylene blue stain than does the body of the bacillus. With the toluidin stain of Ponder, these granu take a red stain, while the body of the organism is blue. is true that this method does give a double staining w the toluidin blue, but the intensity of the staining is variab Ponder recognizes four types of staining with this stai 1. Certain cells do not take the stain at all. 2. Some ce are entirely blue. 3. Some cells are pink or red througho 4. Other cells show a blue protoplasm with red metachroma granules. In the latter group are found the true diphthe bacilli. Frequent use of this method has demonstrated double-staining power, but has not justified Ponder's asserti that the stain is more valuable than Neisser's.

BOOKS ON THE HISTORY OF MEDICINE

To the Editor:—Please supply me with a list of the recent p lications on the history of medicine.

Joel I. Butler, M.D., Tucson, Ariz.

Answer.—The following is a list of histories of medici published within the last twenty-five years:

Baas, J. H.: Outlines of History of Medicine, New York, W. *Jenkins Company, $6.*
Davis, N. S.: History of Medicine, Chicago, Cleveland Press,
Garrison, F H.: Introduction to History of Medicine, Philad phia, W. B. *Saunders Company*, $6.
Gorton, D A.: *History of* Medicine, 2 volumes, New York, G. Putnam's Sons, $6
Mumford, J. G.: Medicine in America, Philadelphia, J. B. L pincott Company, $3.
Mumford, J. G.: Surgical Memories, New York, Moffatt Yard Co., $2 50.
Neuberger, M.: History of Medicine, New York, Oxford U versity Press; Vol. I, $9; Vol. II in preparation.
Packard, F. R.: *History of Medicine in United States, Philad* phia, J. B. Lippincott Company, $4.
Park, R.: Epitome of History of Medicine, Philadelphia, F. Davis Company, $2.
Payne, J. F.: English Medicine in Anglo-Saxon Times, N York, Oxford University Press, $2.90 net.
Walsh, J J.: Catholic Churchmen in Science, New York, Fo ham University Press, $1.
Walsh, J. J.: Makers of Modern Medicine, New York, Fordh University Press, $2.
Walsh, J. J.: *Old-Time* Makers of Medicine, New York, Fordh University Press, $2.
Wilder, R. N.: History of Medicine, Cincinnati, Scudder Bro ers, $3.
Wootton, A. C.: Chronicles of Pharmacy, New York, The M millan Company, 2 volumes, $6.50.

EFFICIENCY OF FORMALDEHYD STERILIZERS

To the Editor:—1. What is the actual efficiency of the "Eri and other similar "sterilizers" consisting of a glass case wi shelves, with a saucer of liquor formaldehydi on the bottom f the sterilization of (*a*) instruments. (*b*) rubber gloves and (dressings?

2 If these sterilizers are efficient, is it essential that the c should close hermetically? R. S. P.

Answer.—It is impossible to state the actual efficiency any of these formaldehyd sterilizers as no experimental e dence on the subject is available. It is generally accepted a *fact that* exposure *to the* vapors of formaldehyd with sufficiency of moisture in the air is an efficient method of disi fection, *provided that* the concentration of formaldehyd great enough. (*a*) With reference to instruments, inasmu as we cannot well be *sure of absolute efficiency, it is desira* that instruments be boiled before using. (*b*) For rub gloves boiling is certainly preferable. (*c*) It is probable th dressings can be disinfected in this way and subsequently dri but the disadvantage of such a method as compared wi sterilization by steam are *obvious.*

2. The case should be air-tight or nearly so.

SODIUM CACODYLATE IN SYPHILIS

To the Editor:—Is sodium cacodylate an efficient anti-syphili even if given in very large doses? J. G. M.

Answer.—Sodium cacodylate has not been used to a su cient extent to determine its true value, though the eviden seems to be that while it is of *service it is not an agent* be relied on alone. The latest article dealing with this subject that we can find (Sodium Cacodylate in Syphilis, *New York Med. Jour.*, March 2, 1912; abstr., The Journal, March 23, 1912), is by L. J. Spivak, who found that it had practically no effect on a Wassermann reaction. He says that while its action is not so rapid as salvarsan, it gives a result not unlike that of salvarsan.

HIGH-SCHOOL CREDENTIALS FOR SALE

Illustration of Irregular Methods by Which Commercially Conducted Medical Colleges Admit Students Contrary to Law

In checking up recently the methods employed in admitting students to several of Chicago's multiplicity of medical colleges, a number of irregularities have been found:

(*a*) Students readily gained admission to these colleges, though they previously had been refused admission to other medical colleges—those which had strictly enforced, for every student admitted, the completion of a four-year course in an accredited high school.

(*b*) Students who had failed to complete work satisfactorily in a number of reputable medical schools and who, therefore, had been refused promotion in those schools, have readily gained advanced standing, without such penalty, in these low-standard colleges.

(*c*) Advanced standing, apparently without the requirement of additional work, has also been granted to students coming from notoriously low-grade medical colleges.

These findings led to a further investigation which revealed the fact that many students had in some way received credentials claimed to be "a high school equivalent" but who had completed far less than four years of work in a standard high school. In fact, it was apparent that some who held such credentials had not attended beyond the eighth grade in the public schools; nevertheless, they had secured apparently with ease, this so-called "equivalent" certificate and had gained admission to these schools.

A CREDENTIAL MILL DISCOVERED

In this investigation a young man posing as a medical student succeeded in unearthing a credential mill, from which, by the payment of $25, a certificate was secured which was supposed to be based on a legitimate examination covering all the branches of the four-year high-school course. The openness with which this "credential mill" was conducted and the ease with which this young man secured his certificate, justifies the belief that those concerned have carried on a highly profitable business and that many of the students enrolled in Chicago's low-grade medical colleges have secured admission on the basis of these or equally questionable certificates. It will be noted that the methods employed were such as to deceive even the most conscientious inspectors of preliminary credentials, unless effective routine methods of verification are followed.

Although the Bennett Medical College is the institution chiefly referred to in what follows, there is reason to believe that credentials equally unreliable have been accepted by at least two other Chicago medical colleges. Bennett Medical College is only nominally the medical department of Loyola University. It is a stock corporation, all the stock being controlled up to a few weeks ago, at least, according to the statement of Dr. Robertson himself, by Dr. John Dill Robertson and Dr. William F. Waugh. We do not believe that Loyola University appreciates the character of the methods employed at the medical school to which it has loaned its name.

WHAT WAS ACCOMPLISHED

The would-be medical student, Mr. W. R. Cowgill (which is not his correct name), assuming to come from an adjoining state, and stating that he had completed only one and one-half years in a high school, succeeded, through Mr. O. T. Owen, registrar of the Bennett Medical College, in securing from the Balfour Johnstone School, apparently the same institution as the Brooks Classical School, a certificate supposed to represent the equivalent of a high-school education. This certificate, which was signed by Mr. John J. Kerwin, County Superintendent of Schools for Kenosha County, Wis., was obtained after a pretense at an examination, both the questions and the answers having been previously furnished Mr. Cowgill. Even then, such writing as was required for the examination was done in his own room. The certificate thus obtained was accepted at the Bennett Medical College, and on it Mr. Cowgill was enrolled as a freshman student in that college. We will allow him to tell the story in his own words.

Statement by Mr. Cowgill:

The following is a brief outline of how I secured a certificate which was issued through the aid of the Bennett Medical College after a fake examination; how it was accepted at this college as equivalent to a high school diploma, and on which I was entered as a Freshman Student.

Those who were parties to the transaction were: (*a*) Mr. O. T. Owen, Registrar of Bennett Medical College and evidently the controller of the Brooks Classical School; (*b*) Mr. Balfour Johnstone, who operates the Balfour Johnstone School and manages the Brooks Classical School at Room 1017, Schiller Building, 64 West Randolph Street, Chicago, and (*c*) Mr. John J. Kerwin of Silverlake, Wis., County Superintendent of Schools for Kenosha County (with or without his personal knowledge of the methods employed).

The Balfour Johnstone School apparently is an institution doing private tutoring, and conducting quiz classes preparing students for civil service examinations and for entrance to medical schools. My experience, however, shows that not all the methods employed were strictly legitimate. This institution and the Brooks Classical School were apparently one and the same; at least the two occupied the same office, Room 1017 Schiller Building, as already stated.

THE CORRESPONDENCE

On September 13, I wrote Bennett Medical College as follows:

PORT HURON, MICH., Sept. 13, 1913.

BENNETT MEDICAL COLLEGE,
Ada and Fulton Streets, Chicago.

Dear Sir:—I want to go to a good medical college and heard about your college. Please send a catalogue. What would I have to do to start and when would I have to begin? Haven't gone to school much but ain't afraid to work. How much does it cost?

Yours truly, W. R. COWGILL,
1418 Sixth Street, Port Huron, Mich.

In response I received the following form letter from Mr. Owen and an application blank:

Sept. 17, 1913.

MR. W. R. COWGILL,
1418 Sixth Street, Port Huron, Mich.

Dear Mr. Cowgill:—In compliance with your favor received we take pleasure in sending under separate cover Announcement for 1913-14 of Bennett Medical College and which we hope will have your careful reading. We wish to especially call your attention to the list of Faculty, being composed of men eminent in the medical world, also the schedules will convince you of the high character of work done both in theory and practice. Bennett is affiliated with one of the leading Universities of the country; its hospital ownings and affiliation make it a power of strength in the way of practical medical training; its equivalent fully serves the needs and requirements of a medical school of its size and importance finally backed by an Alumni counting over three thousand successful practicing physicians.

As a matter of great concern to you, after the present enrollment has been made up, which will be on or about Oct. 15, 1913, Bennett will be advanced to a "five-year school," and necessitating an entrance requirement of one year University work in connection with the High School credits. In consequence, in order to avail yourself of the present "four-year medical course" it will be necessary to have your early enrollment, together with a certified copy of your entrance credits for filing in the College Office. Also of importance, if lacking entrance credits, let us hear from you and accompanied with full advice.

We are mailing under this cover an Information blank. By your filling out same and returning to us, it will facilitate matters and permit of our advising you regarding entrance credits. The

Fall and Winter Term opens TUESDAY, SEPT. 23, 1913; to enter under present conditions (four-year course) means that you should not delay in writing us.

We will appreciate the favor and your every request for information will have our immediate and best attention. We will hope for your early reply.

Sincerely yours, Bennett Medical College,
O. T. Owen, Registrar.

The application blank which accompanied the preceding letter is as follows, the portions which I filled in being shown by italics:

LOYOLA UNIVERSITY

APPLICATION FOR MATRICULATION

The undersigned hereby applies for admission to the *Medical* Department of Loyola University in the *Freshman* class and if admitted to comply with all the rules and regulations of the College.
Date of Application, *Sept. 19, 1913.*
Occupation, *Salesman.*

	Day	Month	Year	
Birth	*31*	*March*	*1885*	Place, *Fort Gratiot, Mich.*

Color, *White.*
Preliminary Education, *St. Clair, Mich., High School. Went first year and part of second, then had to quit and go to work.*
Previous—————— Education——————
Name in Full, *Wm. R. Cowgill.*
Home Address, *1418 Sixth Street, Port Huron, Mich.*
MATRICULATION FEE, $5.00
Approved——————————Dean.
Chicago, ——————————, 19—.

In my application as will be noted, I said that I had only one and one-half years of high school work. The application was returned to Bennett Medical College with the following letter:

Port Huron, Mich., Sept. 19, 1913.

Bennett Medical College
Chicago, Ill.

Gentlemen:—Your letter received. Am returning the application blank filled out. Please let me know soon if I can enter your medical school so I can arrange to come. Was intending to go to St. Louis where I could get fixed all right but would rather stay in Chicago if you can take me as I can get work easily. Can I get my degree in four years? Want to get my diploma earliest time possible and don't want to waste a lot of time on useless high school work.

Please answer soon.

Yours truly, W. R. Cowgill,
1418 Sixth Street, Port Huron, Mich.

The following is Mr. Owen's reply stating that he would take good care of my preparatory credits [See also Fig. 1]:

Sept. 27, 1913.

Wm. R. Cowgill,
1418 Sixth Street, Port Huron, Mich.

Dear Mr. Cowgill:—Your letter and application blank received and after referring same to the Council of the college they state that it will be very satisfactory provided you enter at this time.

We will take good care of your preparatory credits and see that you graduate in the time desired, four years.

Hoping that you will be able to come at once, we remain,

Yours very truly, Bennett Medical College,
O. T. Owen, Registrar.

Note my reply stating that I would enter and pay $25:

Oct. 2, 1913.

Bennett Medical College,
Chicago, Ill.

Dear Sirs:—I got your letter but did not know really what to do. Find I can't get all my money till next January. Can I enter and pay $25 down and $15 or $20 a month? Could pay balance in January. Want to locate in Michigan but am afraid of the Michigan Board. Hear they are awful cranky about a fellow not having a high school diploma. Can't you fix me up with a paper that will go with them? Then can't I clean up this high school business soon after I come? Have enough to pay board, books, etc., for a week or so. After that will need all the time I can get for odd jobs to help pay expenses. Please write soon if this can be fixed all right. Ain't afraid to work but can't afford to come if no chance.

Yours truly, W. R. Cowgill,
1418 Sixth Street, Port Huron, Mich.

Mr. Owen's reply, which follows, advised me that he had referred the matter to the preparatory school:

Oct. 7, 1913.

Mr. W. R. Cowgill,
1418 Sixth Street, Port Huron, Mich.

Dear Mr. Cowgill:—Your favor received and you had best begin at once with the preparatory school to work off a few subjects in advance of your coming and which would meet the requirements of the Michigan State Board, notably 2 yrs. in Latin.

The tuition you desire to pay is entirely satisfactory and as regards working to help meet your expenses, we will have no difficulty along that line, being in a good position to take care of you.

Unless we hear from you, we will refer your name to our preparatory school and they will send you advice regarding all matters.

Sincerely yours, Bennett Medical College,
O. T. Owen, Registrar.

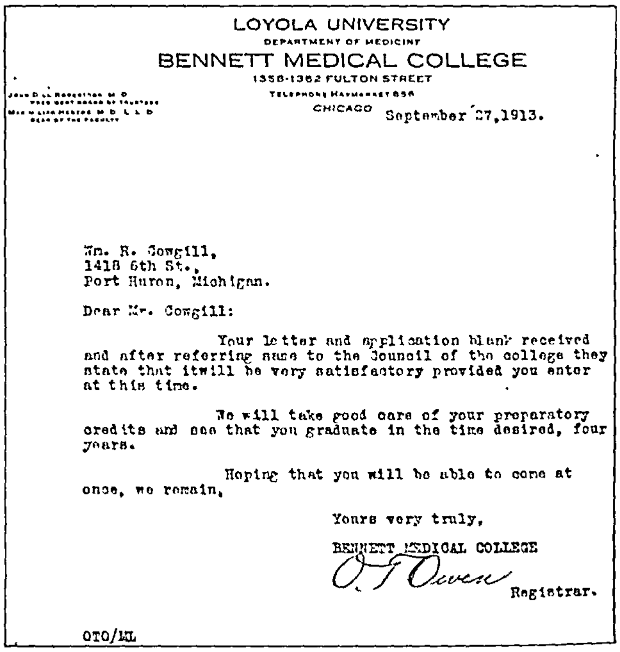
I then wrote as follows requesting that his preparatory school send me advice regarding preliminary matters. I enclosed $5 to pay matriculation fee.

1418 Sixth Street, Port Huron, Mich.
Oct. 13, 1913.

Bennett Medical College,
Ada and Fulton Streets, Chicago.

Dear Sirs:—Intended to come to Chicago the last of this week but find I can't get the money I expected but can doubtless come some time next week. Meanwhile please have your preparatory school send me the advice you suggested regarding all preliminary matters so that I won't have to waste any time after I get there. I must get my diploma in four years as promised in your letter of September 27. Would like to be in shape to practice in Michigan but don't want to waste to much time for the purpose. I am enclosing $5 to pay the matriculation fee. Please send receipt.

Yours truly, W. R. Cowgill.



LOYOLA UNIVERSITY
DEPARTMENT OF MEDICINE
BENNETT MEDICAL COLLEGE

CHICAGO September 27,1913.

Wm. R. Cowgill,
1418 6th St.,
Port Huron, Michigan.

Dear Mr. Cowgill:

Your letter and application blank received and after referring same to the Council of the college they state that itwill be very satisfactory provided you enter at this time.

We will take good care of your preparatory credits and see that you graduate in the time desired, four years.

Hoping that you will be able to come at once, we remain,

Yours very truly,
BENNETT MEDICAL COLLEGE
O. T. Owen
Registrar.

OTO/ML

Fig. 1.—Note in this letter Mr. Owen agrees to take good care of my preparatory credits and guarantees my graduation in four years.

In the following reply Mr. Owen stated that he would take the matter up with the Brooks Classical School, and enclosed me a receipt for my matriculation fee (See also Fig. 2):

Mr. W. R. Cowgill,
Port Huron, Mich.
Oct. 14, 1913.

Dear Mr. Cowgill:—Your favor received and we are mailing under this cover receipt for matriculation for which please accept our thanks.

We will also take your matter up with the Brooks Classical School and you will hear from them by first mail.

We will take good care of your interests and will appreciate your attendance. Hoping that nothing will intervene to prevent your being here next week, we beg to remain,

Very respectfully, Bennett Medical College,
O. T. Owen, Registrar.

THE PERSONAL INVESTIGATION

Thursday, October 23, I called at the business office of Bennett Medical College and saw Mr. Owen. I told him who I was and that I wanted to get through a medical school in four years, if possible, and did not want to waste any time on preliminary courses. He referred to his correspondence and suggested, inasmuch as I only had one and one-half years of high school work, that I enter at once as a special student, make up the preliminary requirements in six or seven months and take an examination about Jan. 1, 1914.

I told him that I could not afford to spend that much time on an uncertainty and that I had heard that he would fix me up in a couple of weeks by a little studying and an examination. He then told me that he controlled the Brooks Classical School and could fix me up. As evidence of this, he took out of his inside pocket a certificate which had been sworn to before a notary public, stating that a certain person (I think Sage was the name), had taken an examination before a county superintendent of public instruction. He assured me that this was sufficient for the Illinois State Board of Health and was all that the law required. He took a folder out of his pocket and from it read that a physician applying before the Illinois State Board of Health must have a high school certificate or its equivalent, and that should an examination be necessary, it must be taken before a state or county superintendent of public instruction. As the certificate above mentioned was signed by a county superintendent of Wisconsin, I asked him if it was good in Illinois. He said it was. In course of the conversation he said there was no law you could not get around. He told me it would not take long for me to get my certificate, as I would be furnished the questions and answers and that Mr. Johnstone (referring to the man in charge of the Brooks Classical School) would fix me up. He urged me to enter the freshman class of Bennett Medical College that afternoon, but I told him that I would prefer to wait until I had talked the matter over with Mr. Johnstone.

October 14,1913.

O T Owen Registrar.

OTO/EL

Fig. 2.—Note that Mr. O. T Owen refers to the Brooks Classical School, which occupies the same office, and is apparently the same institution as the Balfour Johnstone School.

THE CREDENTIAL MILL LOCATED

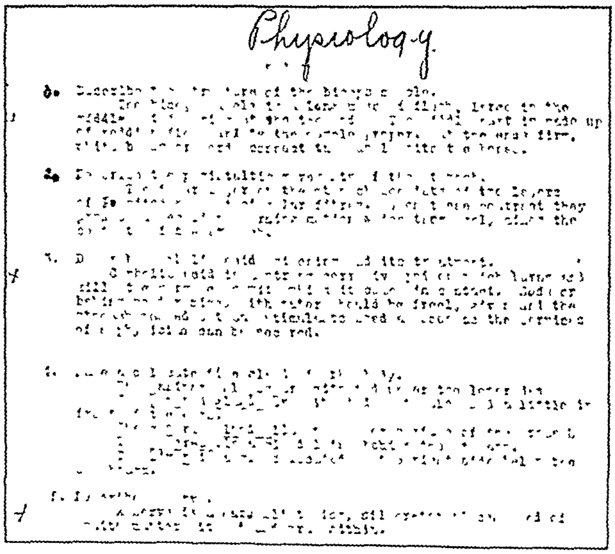
About 5:15 that afternoon Mr. Owen went with me to Mr. Johnstone's office, Room 1017, Schiller Building. On the glass door of this room was the sign: "The Balfour Johnstone School, Brooks Classical School." We met Mr. Johnstone and the three of us talked very quietly about the matter. Mr. Owen stated that I wanted to enter Bennett Medical College, that I had no time to lose, and that he wanted Mr. Johnstone to do what he could for me. Mr. Johnstone explained that he would give me sets of questions which covered the subjects required for the certificate and which had the answers filled in. He said I could easily learn the answers and nobody would know but that I had been attending his school for six or eight months. He emphasized the fact that this was strictly a confidential matter, known only to Mr. Owen, Mr. Johnstone *and myself. Mr. Johnstone said that some man* (apparently referring to Mr. Kerwin) would come to Chicago and give the examination, but that he did not know anything about the preliminary work. He said if he was fortunate enough to get the questions, then I would be the winner. Mr. Owen then told him to let me "go through with the original twelve." I asked Mr. Johnstone how much it would cost and Mr. Owen spoke up and said he would see that I got my certificate for $25. He explained that $15 was to go to Mr. Johnstone and $10 to the one who gives the examination. Mr. Johnstone said that this arrangement was satisfactory to him. Mr. Owen then said I was pretty lucky in getting in now, as next year higher requirements would go into effect.

QUESTIONS WITH ANSWERS GIVEN OUT

I said I would like to get started right away, and with that Mr. Johnstone reached over to a book-cabinet back of me and took off several sheets from a stack of paper that was lying on the top of the books. He gave me several sheets of mimeographed paper which contained the questions and answers for eight subjects, namely: English literature, geometry, botany, civil government, physical geography, *ancient history, medieval and modern history and English* history. He said he would give me the balance when I came again. For each of the eight subjects there were five questions with the answers (see Fig. 3). Mr. Owen told me I had better come in the following Saturday and pay Mr. Johnstone $15, and that I could pay the balance when I got my certificate. I did not go back, however, until Monday, October 27. Mr. Johnstone did not recognize me at first and asked what arrangements he had made with me. I told him in brief what I had come for and then he remembered me. I gave him the $15 as requested by Mr. Owen, for which he gave me a receipt.

I ENROLL AS A MEDICAL STUDENT

The next day, Wednesday, October 29, I went to the Bennett Medical College to enroll. Mr. Owen requested me to fill out another application blank and sign a note for $62.50 for my fees, as I told him I could not pay cash. His young lady stenographer helped me fill out the application and instead of giving my preliminary education as one and one-half years of high school work (see page 478), she told me to insert the words "high school equivalent." My original application blank was then destroyed and the new one placed on file. This change was apparently for the purpose of disguising the fact that my attendance at high school had been for so brief a period.



Physiology

Fig. 3—A reproduction of the examination questions, with the answers, in one of the subjects—physiology.

Having fixed my application blank I was sent to the front office to a Mr. Waugh who had a card made out, placing me in seat 57 and section 1 of the freshman class. I then paid $1 for a locker, and after some difficulty secured one.

Friday, November 7, I paid Mr. Owen $10 for the examination. This, added to the $15 already paid to Mr. Johnstone, amounted to $25, which my preliminary certificate cost me.

Tuesday, November 11, and on several other occasions, I visited the Balfour Johnstone School and was quizzed on some of the subjects on which I was to be examined. I asked Mr. Johnstone for the questions covering the remaining subjects. He told me that Mr. Owen had not sent them down, and asked me to remind Mr. Owen about sending him the additional questions.

ADDITIONAL QUESTIONS SECURED

Wednesday, November 12, complying with the request of Mr. Johnstone, I asked Mr. Owen for the additional questions. He took a bundle of papers out of his desk and gave them to his stenographer, who wrapped them up and gave them to me. In a private place I opened this package and found about twenty-five sets of questions covering the additional six subjects on which I was to take examination. Each paper excepting those for German and American history had five questions with answers similar to those given me Thursday, October 23. The paper for German had only four questions and in the paper for American history the fourth question had been omitted. I tied the papers up again and later delivered the package to Mr. Johnstone. He opened the package and gave me one set covering the subjects of Latin, German, physiology, algebra, physics and American history. I had thus been used as a messenger between the Bennett Medical College and the Balfour Johnstone School (Brooks Classical School). I served in the same capacity on another occasion to be mentioned later.

RECEIVED
11 12 13 $30.00
11 6 13 $10.00
11 15 13 $22.50

Fig. 4.—Copy of the note which was given in payment of tuition fees. This note, as will be seen, was paid in three separate installments.

I paid Mr. Owen partial amounts on the note for my medical college fees, as will be seen, and paid the balance about November 15, when it was returned to me marked "Paid, B. M. C." by his stenographer (see Fig. 4).

HOW THE EXAMINATION WAS HELD

Friday, November 21, I called on Mr. Owen and stated that I was going to Mr. Johnstone's school to take my examination. He asked me as a favor if I would take the examination paper down with me. I agreed and he had his stenographer wrap up two or three hundred sheets of yellow paper 8½ by 11 inches, which he got from another room. Thus not only had examination questions (with the answers supplied) been furnished from Bennett Medical College, but also the paper to be used at the examination. I arrived at Mr. Johnstone's school between 11 and 12 o'clock, but since no one else was there, I left saying I would come back later; I wanted to see who else was to take the examination. I went back that afternoon about 1 o'clock, and found two other young men in his office. I sat at the left side of Mr. Johnstone, while at his right sat the two young men just referred to Each of us was given about twenty-five sheets of yellow paper similar to that I had brought from Bennett Medical College. Up to this time I had understood that the examination would be given by a Mr. Kerwin, but Mr. Johnstone stated that inasmuch as there were only three students, Mr. Kerwin did not think it necessary to come down. Mr. Johnstone said he did not see any use of us boys staying there in his office, but told us to take the paper home, and copy off the answers, and return our examination papers by the following night. He said Mr. Kerwin would not know the difference. Only about fifteen minutes were occupied in securing these instructions from Mr. Johnstone.

I followed the other boys out and found they had also come from Bennett Medical College and the three of us walked back to the college together. They had been furnished with mimeographed sets of questions and answers, which, on comparison, I found were the same as those furnished me. One of the boys stated that he had paid $5 on his certificate, but that Mr. Owen wanted more. The other boy stated that he had paid Mr. Owen $15 and did not think that he would have to pay any more. I had paid $25 to get my certificate. We all worked in the dissecting room that afternoon between 2 and 3 o'clock.

ACTUAL WORK REQUIRED FOR THE CERTIFICATE

I went to my room about 4 p. m. and began work on my examination papers. It took me four or five hours to copy the answers from the mimeographed sheets. My previous attempts at memorizing these answers and the copying of them was the only work connected with the examination. I returned my examination papers to Mr. Johnstone Saturday afternoon, November 22.

Tuesday, December 2, I called at Mr. Johnstone's school for my certificate and was advised that they had not heard from Mr. Kerwin. Thursday, December 4, I again called and Mr. Johnstone said that he had overlooked giving Mr. Kerwin the days of the month on which the examination was supposed to have been held. He asked me if I remembered it, and I told him November 21 and 22. I went back on Monday, December 8, and he told me the certificate had been delayed through an oversight on his part, as he had not sent the questions on one of the subjects to Mr. Kerwin. I called at Mr. Owen's office inquiring about my certificate on December 2, and also December 9, and he told me that he expected it most any day.

I GET MY CERTIFICATE

Monday, December 15, when I called at Mr. Johnstone's office, he went to his desk and pulled open a drawer and took out a roll of certificates. He looked at two or three, and then pulled out mine and gave it to me. I examined it and noticing that subjects were mentioned in it in which I had not taken examinations, asked him if the certificate gave me sufficient credits. He said I surely ought to have rhetoric and told me to take up the matter with Mr. Owen and that I could get questions and answers on any additional subjects. Before calling on Mr. Owen, however, the certificate was photographed and a zinc etching made of it. (See Fig. 5.)

Wednesday, December 17, I called at Mr. Owen's office and told him that I had secured my certificate from Mr. Johnstone but wondered whether it gave me enough credits. I showed him the certificate, and he said I would have to have English grammar, composition and rhetoric. He asked me to let him have the certificate and said he would have Mr. Johnstone fill in the extra credits. He said Mr. Johnstone would not do it for me. Nothing was said about examination questions on these additional subjects (English grammar, composition and rhetoric) nor were examination papers in those subjects ever filled out by me. Mr. Owen stated that I would have to leave my certificate with him anyhow, so it would be in the envelope when Father Spalding, who, I was told, was the superintendent of Loyola University, came to check up the students' credentials.

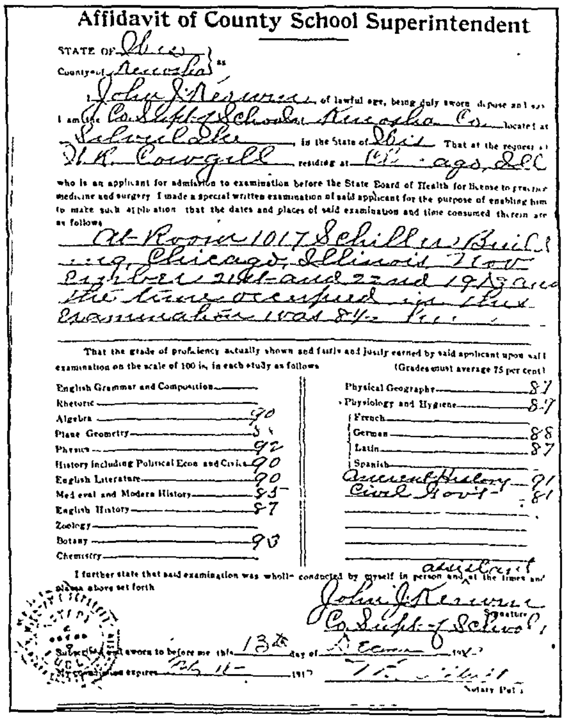
I attended most of the classes from the time I enrolled, October 29, until January 16, when I secured my amended certificate from the Brooks Classical school.

COLLEGE CLEANED UP FOR AN INSPECTION

Thursday, December 18, when I got to the school I noticed that everything was unusually clean. The halls had been carefully swept, the floors had been scrubbed, and clean white cloths had been placed over the cadavers in the dissecting room. This was quite contrary to the usual condition of things. The floor of the freshmen's lounging room in the basement was usually littered with paper, burned matches and cigarette stubs; but all had been carefully cleaned up. It was rumored, and so turned out, that the A. M. A. man was coming to inspect the college, and everybody seemed to be on the jump.

MY CREDENTIALS ARE O. K.'D

January 6, 9 and 12 I called at Mr. Owen's office to see if I could get back my certificate and make sure of the additional credits, but each time I was put off with the excuse that I could not have it as the envelope containing my preliminary credentials had not been O. K.'d. Wednesday, January 14, I again called at Mr. Owen's office, and he told me that the extra grade had been filled in by Mr. Johnstone and that the credentials had been O. K.'d by Father Spalding, whereupon he pointed to an O. K. written on the envelope containing my certificate. By changing the wording of my application blank, therefore, and by securing for me, through questionable means, a certificate of having passed, as required by law, an examination covering all the branches of a high school course, the certificate having been signed by a county superintendent of public instruction, in the presence of a notary public, Mr. Owen evidently succeeded in making Father Spalding believe that I held satisfactory credentials of preliminary education.



Affidavit of County School Superintendent

STATE OF Ohio }
County of Kenosha } ss

I, John J. [illegible] of lawful age, being duly sworn depose and say I am the Co. Supt. of Schools Kenosha Co. located at [illegible] in the State of Ohio That at the request of W. K. Cowgill residing at Chicago, Ill. who is an applicant for admission to examination before the State Board of Health for license to practice medicine and surgery I made a special written examination of said applicant for the purpose of enabling him to make such application that the dates and places of said examination and time consumed therein are as follows

At Room 1017 Schiller Building, Chicago, Illinois Nov eighteen 21st and 22nd 1913 and the time occupied in this examination was 8½ hrs.

That the grade of proficiency actually shown and fairly and justly earned by said applicant upon said examination on the scale of 100 is, in each study as follows (Grades must average 75 per cent)

English Grammar and Composition		Physical Geography	87
Rhetoric		Physiology and Hygiene	87
Algebra	90	French	
Plane Geometry	85	German	88
Physics	92	Latin	87
History including Political Econ and Civics	90	Spanish	
English Literature	90	Ancient History	91
Medieval and Modern History	85	Civil Gov't	81
English History	87		
Zoology			
Botany	93		
Chemistry			

I further state that said examination was wholly conducted by myself in person and assistant at the times and places above set forth

Co. Supt. of Schools

Subscribed and sworn to before me this 13th day of Dec. 1913
My commission expires Feb. 11 1917

Notary Public

Fig. 5.—A reproduction of the certificate secured after a make-believe examination had been gone through with. As will be seen, no grades are entered for the two subjects, English grammar and composition and rhetoric. Note also that the certificate has been sworn to in the presence of a notary public. Compare this with Figure 6.

I GET MY AMENDED CERTIFICATE

I tried repeatedly to get possession of the amended certificate and finally succeeded on Jan. 16, 1914. (See Fig. 6). On giving me the certificate Mr. Owen said he did not have time to make a copy of it, but that I could make a copy of it when I got home and send it to him. I signed a receipt, and his stenographer gave me the certificate. On examining it I found that grades for English grammar and composition and for rhetoric had been filled in—for subjects in which I had not even gone through the form of an examination. It is apparent that Mr. Owen was fully aware that the changes had been made, as they were made at his request. These marks were placed on the certificate between the time I gave the certificate to Mr. Owen, Wednesday, December 17, and when I received it back on Friday, January 16. (See Fig. 4.)

Fig. 6.—The same certificate as shown in Figure 5 as it appeared when it was returned to me by the Registrar of Bennett Medical College. Between the time I gave it to him (Dec. 17) and the time the certificate was returned to me (Jan. 16) grades had been filled in for the two subjects, English grammar and composition, and rhetoric. I had not even gone through the form of an examination in these two subjects.

Questions and Answers Reproduced

Questions with the answers added were supplied for fourteen subjects. The paper on physiology has been reproduced in Figure 1. Below are printed the first question and answer of seven subjects.

GEOMETRY

1.—Define and give an example of a postulate and of an axiom.

A postulate is a construction admitted to be possible. Example: Let it be granted that a circle may be described with any center at any distance from that center.

An axiom is a statement admitted to be true without proof. Example: The whole is greater than its part.

PHYSICS

1.—What is specific heat? What is Dulong and Petit's law in regard to the connection between specific heat and atomic weight?

Specific heat is the amount of heat required to raise the temperature of any substance through one degree as compared with the amount of heat required to raise the temperature of the same weight of water through one degree.

Dulong and Petit's law states that if the atomic weights of all the elements be multiplied by their specific heats, the result is a constant.

AMERICAN HISTORY

1.—Speak of the differences in ideas concerning the constitution that the federalists and antifederalists had.

The federalists endorsed the Constitution but wished to read into it more power for the Central government, while the antifederalists accepted it with limitations and were anxious to restrict the power of the Central government within the narrowest bounds.

BOTANY

1.—What are the organs of vegetation?
Root, stem and leaves.

PHYSICAL GEOGRAPHY

1.—What is the "fall line" and why are so many cities situated on it?
The "fall line" is an imaginary line running parallel to the Atlantic Ocean from Pennsylvania southward. It marks the place where the Continental block suddenly dips, and lands between it and the sea being low-lying. Cities are situated upon it because all rivers crossing it have falls and thus supply power. The rivers are navigable up to this line and the cities are seaports and at the same time have easy communication with the interior.

ANCIENT HISTORY

1.—Write briefly of the Assyrian Empire.
The Assyrian Empire was founded in 1250 B. C. It rapidly increased in power and subjugated Babylon, Phoenicia, Judaea and Egypt. The Assyrians had a long line of warlike kings, among whom Tiglath Pileser, Sargon and Sennacherib were the most important. They were a military people and cared little for art, science or literature. Their architecture and religion were both borrowed from the Chaldeans. They were a Semitic people and their language resembled that of the Hebrews Their chief city was Nineveh, situated on the east bank of the Tigris River.

CIVIL GOVERNMENT

1.—Describe two important institutions of our national government that are not provided for in the constitution.
Two important institutions of our national government not provided for by the constitution are the President's cabinet and the national conventions for nominating presidential candidates. The President's cabinet consists of nine officers, each of whom is at the head of a department, while collectively they serve as an advisory board for the President

The nominating conventions of the two great political parties are made up of delegates from the various states, each state being entitled to twice as many delegates as it has members of congress. The delegates are chosen by state conventions.

Book Notices

BERIBERI. By Edward B Vedder, A M., M D, Captain Medical Corps, U. S. Army The Cartwright Prize of the Alumni of the *College of Physicians and Surgeons, Medical Department of Columbia University*, New York, for 1913, and published by Permission of the Surgeon-General of U. S Army Cloth. Price, $4 net. Pp 427, with 51 illustrations. New York: William Wood & Co., 1913.

This book presents what is known in regard to beriberi. The history of the disease, its distribution, pathologic anatomy and clinical features, its relation to rice and its etiology as revealed by recent investigations, infantile beriberi, ship beriberi, epidemic dropsy, and theoretical and practical considerations are the principal subdivisions. There are an extensive bibliography and good indexes. Beriberi being "a disease resulting from faulty metabolism, usually only seen in those persons who eat rice as the staple article of diet" and caused by the "deficiency of certain vitamins in the food." Captain Vedder urges the appointment of an international commission to discuss the ways and means necessary to abolish the use of highly milled or polished rice, which no longer contain the necessary vitamins. As the disease is preventable by such seemingly simple means, this recommendation certainly is a sensible one. The book is heartily commended to all who are interested in beriberi and similar diseases. If a new edition is wanted the author should revise the book carefully with a view to improving the literary form.

A [illegible] x PHYSIOLOGY. By Walter B. Cannon, A.M., [illegible] son, Professor of Physiology in the Harvard [illegible] ond Edition. Cloth. Price, $2.50. Pp. 137. [illegible] University Press. 1913.

This is an outline of carefully selected and arranged experiments for a laboratory course in physiology, especially for medical students. The ideals and aims of laboratory instruction are well stated by Dr. Cannon in these words: "That the student may receive the greatest benefit from the discipline of his study, it is essential that he be placed as far as possible on his own resources. He should be required to make and record his own observations, draw his own conclusions, and be urged to suggest further experiments to test these conclusions." The author does not strictly follow this ideal in the book, because in many instances the experiments are outlined in such great detail that nothing is left for the student save the mechanical work. The outline contains no experiments or demonstrations on the organs of internal secretion. It would seem that a laboratory course in physiology in all our first-class medical schools ought to include some work in this important chapter of physiology.

HANDBUCH DER SPEZIELLEN PATHOLOGIE DES HARNS. Von Dr. Med. Ferdinand Blumenthal. Universitätsprofessor in Berlin. Paper. Price, $4.25. Pp. 492. New York: Rebman Company, 1913.

This excellent work is a continuation of the author's "Pathologie des Harns am Krankenbett," published about ten years ago. It is rather too large and extensive for the general student or practitioner, but should be found a valuable addition to the library. The author has not only set himself the task of discussing, both from the practical and theoretical points of view, the many variations to be found in the urine in widely diversified conditions of a local or general nature, but has also elaborated the diagnostic, prognostic and therapeutic deductions to be drawn therefrom. That he has succeeded admirably in carrying his work to a satisfactory completion is evidenced by perusal of the book. The subject-matter is presented in a clear, forceful and comprehensive manner, while the arguments and conclusions are convincing. Bibliographic references are numerous, but it is to be noted that the rather voluminous work of American workers on the various subjects connected with the urine has been largely overlooked. This is, however, not a personal failing of the author, but is, rather, a German custom. There need be no hesitancy in recommending this book to the special worker in this field, as it covers the ground in a thoroughly satisfactory manner and gives an enormous mass of detail. For the general worker it should prove valuable as a reference work.

THEORIE UND PRAXIS DER INNEREN MEDIZIN. Ein Lehrbuch für *Studierende und Aerzte. Von Dr. Erich Kindborg. Volume III.* Cloth Price, 13 marks. Pp. 751, with 75 illustrations. Berlin: S Karger, 1914.

In this volume Kindborg brings to a successful conclusion his attempt to combine the needed knowledge of the fundamental medical sciences with the clinical description of disease. The account of diseases of the kidneys is preceded by a considerable treatise on the examination of the urine. The author even includes the methods of cryoscopy and the determination of the electrical conductivity of the urine, which he acknowledges are too time-consuming and technical for use by the general practitioner. The subject of cystoscopy is illustrated by cuts from actual photographs showing the condition of the bladder in various diseases. The examination of the blood is fully described and well illustrated. The general character of the articles corresponds to that of the first two volumes. The whole forms a valuable handbook for the German reader.

Medicolegal

Having Syphilis Not Conduct Unbecoming an Officer

(People ex rel, Langdon v. Waldo, Police Commissioner (N. Y.), 143 N. Y. Supp. 818)

The Supreme Court of New York, Appellate Division, Second Department, says that this relator was dismissed from the police force of the city of New York on a finding of guilty on charges of conduct unbecoming an officer. The specification was that he had contracted syphilis at some time in the past, and was then affected with it. There was proof in the record that syphilis is an infectious disease, and the court may take judicial notice that it may be contracted by a person entirely innocent of sexual commerce with one tainted therewith. No attempt was made to show that the relator contracted directly this disease as the result of immoral practices or of loose conduct. On the other hand, he was not suffered to testify that such was not the cause of his affliction, if that ailment was established to the satisfaction of the trial commissioner For aught that appeared, the punishment of dismissal was inflicted for innocent misfortune, not conscious misdoing If the relator was tainted with the disease to the peril of present association with other members of the force, that was a matter for physicians to regulate The determination is annulled, and the relator is reinstated, with $50 costs and disbursements

Manslaughter Through Fasting Treatment or Withholding of Food—Admissible Evidence

(State vs Hazzard (Wash), 134 Pac R 514)

The Supreme Court of Washington affirms a judgment of conviction of the defendant of manslaughter The information charged that she did, on Feb 28, 1911, and on divers days between that date and May 20, 1911, wilfully, etc, kill one Claire Williamson by depriving and keeping from her all food and sustenance except the juices of fruits in quantity not to exceed two fluidounces daily, and the broth of vegetables not to exceed eight fluidounces in quantity daily on said days and dates, said food not being sufficient in quantity and quality to sustain life in the said Claire Williamson's body, she being in the care, custody and control of the defendant, etc

Claire and Dora Wllliamson, 34 and 37 years of age, respectively, answered an advertisement of the defendant, and the former conducted correspondence with the defendant during which the latter forwarded to her a book on "Fasting for the Cure of Disease" written by the defendant, and also a pamphlet giving an account of the defendant's sanatorium in Seattle The women finally decided to go to the sanatorium and take a course of treatments, for which they were to pay $60 a month They were then in reasonably good health Dora suffered occasionally from rheumatism and indigestion and Claire from a displacement of the uterus which would readily respond to treatment The treatments consisted in massage or rubbing, the abstaining from food, except fruit juice, asparagus water and vegetable broth with a small bit of butter therein about as large as the thumb nail a warm bath practically every day, and an enema of from four to six quarts of warm water each day The women constantly grew weaker and more emaciated During this time the defendant repeatedly inquired into their family and business affairs, their income, etc, and induced them to give up their papers, money and jewelry for safekeeping by the defendant Claire Williamson, with the help of defendant's attorney, executed a codicil to her will bequeathing an annuity to defendant's sanatorium and signed an order for the amount of her bank balance Less than a month later she died Both women at that time weighed less than half as much as at the beginning of the treatment When they asked for food the defendant told them that the poison was not yet entirely out of their systems, and that to take food might result fatally

The court holds that the information was legally sufficient to charge a crime It did not charge the crime to have been committed on different days but charged continuing conduct between the dates mentioned producing death at a certain time Neither was the information bad for failure to charge a legal duty on the defendant to furnish food The defendant was charged with the crime of murder in the first degree, in that with premeditated design she did kill and murder Claire Williamson by the depriving and withholding from her of food and sustenance except, etc, which produced death This was not the charging of a crime by failure to perform a duty but it was the charging that the crime was committed by an affirmative positive act Under such a charge it was not necessary to allege a duty to furnish food But if such an allegation were necessary it was plainly found in the information, wherein it was said that Claire Williamson was in the care, custody and control of the defendant, who had undertaken to care for her and to provide sufficient food and sustenance to sustain life

Nor was there error in admitting evidence showing transactions of the defendant with Dora Williamson the treatment she received, and the effect thereof The evidence as to Dora was competent for the purpose of showing a plan or scheme on the part of the defendant to effect the death of both of the girls The proof of such plan or scheme would afford grounds for the inference that the defendant was actuated by a criminal intent Besides, the two girls were together when the contract for the treatment was made, they received the same treatment, occupied the same suite of rooms, and were so intimately associated as to make the treatment which the two girls received substantially one transaction Where the conduct complained of constitutes one continuous transaction, evidence of all the facts and circumstances connected therewith is relevant

Certain physicians, in answer to hypothetical questions, were permitted to testify as to the degree of medical skill and care used by the defendant in treating the deceased Complaint was made of this testimony by the defendant, because it was contended that it tended to prove the crime of malpractice, while the defendant was charged with murder in the first degree by the withholding of food The defendant was charged with murder in the first degree by the withholding of food with the premeditated design to produce death Within that charge were included two lesser crimes, that of murder in the second degree, and manslaughter If the defendant did not withhold food with a premeditated design but did withhold food through failure to exercise that degree of care which the law imposes on one practicing her profession, then she would not be guilty of murder in the first degree, but would be guilty of a lesser crime The evidence, therefore, was admissible under the charge as laid in the information

---

Society Proceedings

NATIONAL CONFERENCE ON RACE BETTERMENT

Held at Battle Creek, Mich, Jan 8 12, 1914

Under the presidency of Dr Stephen Smith, New York

Dr J H Kellogg, Battle Creek, Mich The object of this conference is the advancement of human welfare The questions to be discussed do not relate to sect or section, finance or politics The purpose of the conference is not to formulate conclusions or propagate doctrines, but to raise questions of world wide significance, and to set in operation methods of inquiry which it is hoped will lead to a disclosure of facts of tremendous importance

The Basic Principles of Race Betterment

Dr Stephen Smith, New York The objects of the conference are (1) to assemble evidence as to the extent to which degenerative tendencies are actively at work in America and (2) to promote agencies for race betterment This includes everything which affects unfavorably the normal development of the human race The second object opens a wide field, as these agencies are innumerable The question as to the effectiveness of any agency will cause great diversity of opinion unless we have a common object in view, and that we have not a common object in our charitable efforts is generally recognized Ignorance is the greatest obstacle to success in the treatment of the defective and dependent Two methods of preventing the propagation of degenerates are practiced—sterilization and segregation These methods are necessarily limited in application

Prevention of Arteriosclerosis

Dr Louis F Bishop, New York Never has the study of arteriosclerosis seemed to be of so great importance as at present, because never before has this disease played so important a part in undermining the efficiency and shortening the lives of workers The mortality from arteriosclerosis is more than double what it was thirty years ago In 1910, one hundred thousand persons died of circulatory disease in this country Arteriosclerosis is a disease of the whole body, characterized by irritation and destruction of the cells, which are replaced by connective tissue It is caused by a great nervous strain, an infectious disease, a surgical infection, or some form of acute food poisoning. From that time the cells are sensitive to proteins. So long as the supply of the special protein continues, the irritation of the cells is kept up, leading to destruction and progressive sclerosis. Impairment of function follows, greater demands are made on the capillary organs, and eventually there is development of the picture of chronic Bright's disease or apoplexy. If at any time it is possible to remove the offending protein the man is capable of being well. The prevention of arteriosclerosis depends on the avoidance of these causes, on the study of food relations and on the institution of a strict regimen. Arteriosclerosis is usually discovered by a life-insurance examiner or a physician who has been treating the patient for some other ailment. It is seldom the result of a single cause. We should adopt the European custom of a combination of vacation and visit to a cure resort. Race betterment must always be a matter of the improvement of the individual. Arteriosclerosis is not a neighborhood enemy—it is your enemy.

The Significance of a Declining Death-Rate

Mr. Frederick L. Hoffman, Newark, N. J.: The present estimated population of the world is approximately 1,750,000,000, equivalent to a density of 34 persons per square mile. The actual annual increase in population is approximately 13,000,000, or at the rate of 7.7 per thousand. The corresponding rate of annual population increase for the United States is not quite 20 per thousand, and the corresponding density 32 persons per square mile. The world's population is increasing rapidly, because of a decline in the death-rate which more than offsets the decline in the birth-rate. During the last thirty years, the general death-rate of the principal civilized countries has declined 24 per cent., from 23 per thousand to 19. The decrease has been most pronounced in the Netherlands, where the present death-rate is only 63 per cent. of the rate prevailing thirty years ago. The corresponding figure for the registration area of the United States is 76. In 1880 the estimated death-rate of the registration area was not quite 20, whereas for 1912 the rate was a little less than 14. A corresponding decrease has been observed for all the principal large cities of the civilized world. During the French administration of the Panama Canal Zone, the death-rate of employees was 61 per thousand, which under American administration has been reduced to 9, and achievement probably without a parallel in sanitary history. The death-rate of non-native British officers in West Africa has declined since 1905 from 28 to 12 per thousand.

In contrast to a remarkable decline in the tuberculosis death-rate in the United States during the last thirty years, there has been a persistent increase in the death-rate from cancer, which to-day is perhaps the most serious menace to the health and longevity of the adult population. A declining death-rate accelerates growth in population, which in turn necessitates conservation of food-producing resources; improvements in agriculture; reduction in economic waste and utilization of waste products; rational control of marriage, fecundity and divorce; physical training of the young and medical supervision of schools and factories; improvements in local health administration, and coordination of health-promoting public and private agencies and institutions. If the prolongation of life is to be really worth while, the present disharmonies of human existence must be eliminated.

Need of Thorough Birth Registration for Race Betterment

Mr. Cressy L. Wilbur, Washington, D. C.: Vital statistics are the bookkeepers of health, and yet in the large proportion of this country the registration of deaths is so useless that we cannot have any statistics in regard to it. Since 1900, however, we have been making a good deal of progress as regards the registration of deaths; but in birth registration there is rather a different picture. The only states in which the registration of births was practically complete in 1911 were Massachusetts, Rhode Island and Connecticut. Michigan had no vital statistics until 1898, when the new death-registration law went into effect. The birth-registration law was not passed until 1905, and went into operation in 1906. If we believe in ourselves as Americans, we should be apprehensive at times about the day when the difference between the birth-rate and the death-rate is blotted out.

NEW YORK NEUROLOGICAL SOCIETY

Stated Meeting held Dec. 2, 1913

(Continued from page 407)

A Case of Brain Neoplasm with Unusual Features

Dr. Louis Casamajor: A negress, aged 14, was admitted, March 7, 1911, with the history of failing sight and hearing, and partial inability to use the right arm and leg. Her symptoms dated back several months and were growing progressively worse. The patient's family history was negative. With the exception of measles in infancy, the child had always been in good health until August, 1910, when she began to complain of headaches, and became cross-eyed. Glasses were prescribed and her symptoms disappeared within six weeks.

In November, 1910, it was noticed that the child slept more than usual and complained of occasional headaches. A month later there was some loss of function in the right arm; the fingers were stiff and numb, and within a fortnight she began to complain of weakness of the right knee and stiffness of the leg. Subsequently, her sight and hearing became impaired and grew progressively worse. Physical examination showed a dull, undersized negress, with a well-marked right hemiplegia, with increased reflexes on this side but no Babinski. An examination of the eyes showed papilledema of about 3 or 4 diopters on each side, with beginning atrophy. Vision was 20/70, right and left. The visual fields were normal; the Wassermann test was negative, as was also the urine.

Operation was performed, March 11, 1911, by Dr. Charles A. Elsberg. A right subtemporal decompression showed that the intracranial pressure was markedly increased. The operation was followed by a hernia cerebri, which grew to the size of a croquet-ball, and the patient's condition became progressively worse. She gradually became totally blind, and could hear only very loud sounds. Her right hemiplegia progressed, and by June, 1911, she was practically bedridden, blind and deaf. In September, the mother, who objected to the large hernia cerebri chiefly on cosmetic grounds, began bandaging the head tightly. With this, the patient immediately began to improve. The hernia became smaller and the child much brighter. The sight and hearing gradually returned, but the hemiplegia remained about the same, and at present the girl is able to see as well as before the operation, although the optic disks look very much atrophied. There is no deafness of any account. The hemiplegia is evident, the right arm being more affected than the leg. She walks with a slight right limp, while the right hand is contracted and useless. The decompression opening is soft, and there are no evidences of any increased intracranial pressure.

DISCUSSION

Dr. B. Sachs: More than ten years ago I saw a case in which operation had been performed to relieve symptoms of intracranial pressure similar to those in the case shown by Dr. Casamajor, which were attributed to the presence of a neoplasm. When the skull was trephined and the dura incised, a vascular tumor of enormous size presented itself. On account of the patient's condition, no attempt was made to remove the growth. The patient recovered from all her symptoms, except that there was no improvement in the double optic atrophy, which had existed prior to the operation.

Dr. I. Abrahamson: There was possibly a cyst near the ventricle, which, aided by the pressure applied, may have emptied into the ventricle; or else a localized posterior basic serous meningitis, with retention of fluid in the larger cisterns; here the increased pressure from without was the means of reestablishment of the circulation of the cerebrospinal fluid.

Dr. Foster Kennedy: In spite of the good results in this case I do not think that pressure on these hernial protrusions can be regarded as a safe therapeutic measure.

A Case of Muscular Atrophy on a Syphilitic Basis

Dr L Casamajor: The patient was a man aged 28, with paralysis and marked atrophy of the muscles of the right shoulder girdle and arm The patient's previous history was negative, except for a syphilitic infection six years ago, which was insufficiently treated About the end of September, 1913, he noticed that his right arm and shoulder were getting weak He first had difficulty in reaching objects over his head This weakness gradually increased, and in the middle of November he was compelled to give up his work, as he could no longer raise the arm

Physical examination, November 24, showed a well built and nourished young man with marked atrophy of the right arm and shoulder girdle muscles. There was total flaccid paralysis of the deltoid and other shoulder girdle muscles Extension of the elbow was fairly strong, but flexion was practically lost The forearm and hand muscles were much weaker on the right than on the left side Measurements showed that the right arm was 1 inch smaller in circumference than the left The reflexes were much diminished in the right arm. There was no sensory loss. The electric reactions showed a partial reaction of degeneration in the right shoulder girdle muscles, and the other muscles of the right arm were electrically hypo excitable There were no abnormal signs in the rest of the body

Serologic examinations gave the following results blood serum, Wassermann positive, cerebrospinal fluid, Wassermann positive, globulin normal, cells, 149 lymphocytes per cubic millimeter. The patient has made slight improvement under active antisyphilitic treatment.

DISCUSSION

Dr Frederick Tilney: I have seen two cases of muscular atrophy with positive Wassermann reactions in the blood and spinal fluid In both instances the atrophy was progressive The trouble started in the shoulder girdle, and then extended to the biceps and triceps and to the muscles of the forearm and hand One of the cases, after eight years, showed distinct involvement of the sternocleidomastoid and trapezius, and the man now has the characteristic deformity resulting from the involvement of those muscles In one of the cases, that of the longest duration, the muscles showed complete reaction of degeneration, while in the others there were some indications of degenerative changes in the muscles.

SOUTHERN SURGICAL ASSOCIATION

Twenty Sixth Annual Meeting, held at Atlanta, Ga , Dec 16 18, 1913

(Continued from page 404)

End-Results in Operations for Cancer of the Breast

Dr E S Judd, Rochester, Minn Results in operations for cancer of the breast are as good as, if not better, than results in operations for cancer elsewhere The prognosis in younger persons who received the benefit of an early operation was better than we had expected The prognosis is variable in a certain percentage. An extensive external involvement may give a fair prognosis, while a slight external lesion may terminate early from internal metastasis Metastases may occur many years after the operation, though in the great majority of instances they will appear in the first few years, if at all The difference between the percentage of patients living over three, five and ten years is not so great as might be expected, but this is because most patients who die of the disease die within the first three or at least the first five years Five years without recurrence means a very small probability of trouble after that.

Hydrocephalus Internus: Lumbar Drainage

Dr Herbert P Cole Mobile, Ala By a meningocele sac formed above a spina bifida I attempted to drain a case of hydrocephalus internus through the sac into the lumbar muscles The drainage was maintained for two weeks without leakage and with relief of the pressure symptoms The child died on the twenty sixth day, from obstruction in the sac

Surgery of the Pancreas

Dr. R C. Coffey, Portland, Ore The peritoneum must be brought to the field of operation in all direct pancreatic surgery. Fat necrosis can occur only when the pancreatic fluid is delivered directly into the extraperitoneal fat Pancreatic fluid is no more dangerous than bile to the peritoneum, provided ample drainage is used to deliver it to the surface at once The pancreatic duct seems to depend on contiguous pancreatic tissue for its nutrition, and, therefore, is not adapted to direct implantation into the intestine. The cut end of the pancreas, carrying an open duct, may be implanted into a loop of intestine with the same assurance that an intestinal anastomosis is made There is a marked tendency of the pancreatic ducts to reestablish continuity around a gap or an obstacle provided the pancreatic fluid is temporarily delivered to the surface If the head of the pancreas is removed and the open end brought to the surface, a pancreatic fistula results which usually closes in a few weeks The secreting portion of the gland is rapidly destroyed leaving a fibrous cord which contains many islands of Langerhans

Pyloric Stenosis in Infants

Dr James F Mitchell, Washington, D C · My experience has been limited to three cases All came to operation early only one patient having reached any degree of emaciation, weighing 5 pounds, 6 ounces, a loss of over 3 pounds since birth. Two were operated on at 7 weeks and the third at 6 weeks of age A posterior gastro enterostomy was done in each instance The pylorus always presented the typical stony hard, olive shaped tumor apparently with occlusion of the lumen They are now healthy, normally developing children, three and one half years, two and one half years, and eight months after operation I have secured a roentgenogram of the second case which shows, after two and one half years, that bismuth is leaving the stomach through the stoma and none by way of the pylorus.

Excision of the Clavicle and First Rib for Malignant Disease

Dr R E Fort, Nashville, Tenn · Primary sarcoma of the clavicle is a rare condition, and the earlier the diagnosis and the more radical the treatment, the better the chances for complete recovery Partial excision of the clavicle or first rib should not be practiced for malignant disease The danger of local or general metastases is very great, and as division of the bone increases this hazard, excision should be made with the bone intact Because of the favorable results obtained in the few cases of sarcoma of the clavicle and the larger number of sarcomas of long bones, it is advisable to use the mixed toxins of erysipelas and *Bacillus prodigiosus* for two or three months after operation Under modern aseptic conditions the mortality for excision of the clavicle and excision of the first rib should be comparatively small, and considering the fate of the patients who are denied surgery, the opportunity of relief by surgery is mandatory.

Congenital Tumors of Neck

Dr C. E Caldwell, Cincinnati · Critical study of these tumors has shown that not all congenital tumors of the neck are branchiogenic From the contributions of Savelli and Florence Sabin, it seems that the evidence adduced proves that the lymphatic cavities described by Veau, and the jugular sacs described by Sabin, are but different interpretations of the same histologic facts, and that in these lymphatic cavities or perhaps more accurately speaking, jugular sacs, we have the fetal *Anlagen* which result by arrested evolution, in the multilocular serous cysts, the nature and disposition of which correspond most accurately with that of these sacs The absence of a true endothelial investment of the sacs or cysts may be explained on the theory of atrophy from intracystic pressure.

Significance of Pain in the Right Iliac Fossa in Young Women

Dr Randolph Winslow, Baltimore: I have come to believe that in young women, unless the symptoms of appendicitis are frank and clear, the condition is probably something else. Pain and tenderness in the right side, without rigidity, elevation of temperature and leukocytosis is usually not appendicitis Again apparently severe and long continued pain in the right side in girls is more likely to be neurotic than appendiceal Pain may also be reflected from the pelvic organs or some of the other viscera, and the primary seat of the disturbance might be determined by a more careful examination I think that we frequently operate too hastily on a diagnosis of appendicitis, without considering sufficiently the other possibilities in the case

Postoperative Acute Dilatation of the Stomach

DR E P. HOGAN, Birmingham, Ala . I have used the following treatment in my own cases The stomach tube is inserted and the stomach emptied of all contents and irrigated with normal salt solution until the water returns clear The patient is placed in the horizontal right lateroprone position This position is in every way convenient and comfortable Continuous proctoclysis is given Everything by mouth is excluded until symptoms are entirely relieved From 1/60 to 1/30 grain of strychnin and 2 grains of spartein are given every four hours If the patient is not prostrated and is nervous and restless, sufficient morphin is given to produce comfort and sleep In some cases it may be necessary to repeat the washing of the stomach and morphin from four to twelve hours later It should be repeated as often as indicated

Extensive Intestinal Resection

DR RAYMOND C TURCK, Jacksonville, Fla I removed 10 feet, 10¾ inches of ileum, together with the cecum, and the ascending and part of the transverse colon because of dense adhesions, numerous partial obstructions, fecal fistula and multiple sinuses The work was done in three stages Serious metabolic disturbances and diarrhea followed Studies of the metabolic processes, eight months after the ileum resection, showed that a probable compensatory hyperplasia of the intestine with consequent compensatory production of enterokinase had taken place, enough, with a regulated diet, to digest thoroughly and assimilate carbohydrates and a moderate amount of fats, but not enough to care for proteins fully A measured diet, adjusted according to caloric values, and through metabolic examination of feces controlled the diarrhea and caused a decided gain in strength and weight Medication had no effect on the diarrhea

Catgut as a Skin Suture

DR WILLIAM PERRIN NICOLSON, Atlanta, Ga The method of closing wounds advocated is the continuous running suture of 00 catgut placed at intervals of from ½ to ¾ inch and passing beneath the skin into the subcutaneous fat, which permits the wound line to fall into perfect apposition, while at the same time the edges can be pulled apart at any point between the stitches This permits of drainage directly between the wound edges into the dressings, doing away with the necessity for a drain, and the blood serum drying in the gauze next to the wound makes a perfect aseptic covering, practically impervious to air and water Such wounds may be left without disturbance until healing is complete, when the dressing is removed permanently All classes of wounds, including scalp wounds, hernia operations, breast amputations, and kidney operations, are closed thus with chromic catgut and left until healing is complete The catgut employed is that sterilized without chemicals, as it has been found that those sutures which contain iodin and mercurial salts have proved irritating to the tissues immediately surrounding the suture

Conservative Treatment of Undescended Testicle

DR ALEXIUS MCGLANNAN, Baltimore The important questions to be decided regarding the conservative treatment of undescended testicle are, first Is the non descended testicle worth saving? Second, is it technically possible to bring such a testicle into the scrotum in a manner that will preserve its vitality? A study of sixteen cases in which I operated, the histology of seven undescended testicles removed by several other operators, and the literature on the subject proves that an affirmative answer should be given to both questions

1 **Pharmacologic Action of Ecbolic Drugs.**—According to Lieb ergot owes its pharmacologic action to several constituents, of these, ergotoxin alone is specific Beta imido azolylethylamin, parahydroxyphenylethylamin, and the other sympathomimetic amines are products of the putrefaction which occurs during the manufacture of galenical preparations Each constituent has a distinct pharmacologic action, stimulation of the uterus is characteristic of them all In obstetrics at least, Lieb claims, no single active principle can replace active preparations of whole ergot

Extracts of the posterior lobe of the pituitary gland stimulate all smooth muscle It has been suggested that the active constituent of the infundibulum is the hormone which initiates normal labor The extract of the posterior lobe of the pituitary is the most reliable ecbolic which the obstetrician has at his command Its promiscuous employment during labor is strongly condemned by Lieb Because of the stimulating action of quinin on the isolated uterus it may be employed to induce or strengthen labor pains The improvement that follows the use of the iso quinolines in menorrhagia and metrorrhagia Lieb believes is due not to changes in the circulation or in coagulation time, but to a direct action on the uterus Fluid extract of viburnum stimulates the isolated uterus Its action in dysmenorrhea is therefore not due to an effect on the uterus but to a depression of the central nervous system

2 **Uterine Fibroids** —This paper is a plea for the early removal of all uterine fibroids Barrows has tried every form of electrical treatment, from the electrolysis of twenty years ago to the Roentgen ray of to day, and every variety of internal therapy and he is satisfied that the only correct treatment for these growths is removal

3 **Pelvic Inflammatory Disease** —The histories of two hundred patients who have been treated surgically during the last four years in the gynecologic department of the University Hospital at Ann Arbor, for inflammation of the pelvic structures, were studied by Cummings Gonorrhea leads the list of causes, showing 38 per cent Sepsis following criminal and accidental abortion, or confinement accounts for many of the most virulent and fatal cases of pelvic inflammatory disease The treatment outlined by Cummings, briefly, is Pelvic infection, like other infections, requires general measures, such as absolute rest, stimulation of the emunctories, locally cold applications give relief In the acute stages, hot, long continued vaginal douches hasten the softening of exudates, lessen congestion and relieve pain When a definite mass can be outlined and pus is undoubtedly present, a posterior colpotomy gives the best results Many patients return for a radical removal of the involved organs several months after the posterior colpotomy has been done By that time the inflammation has lost its virulency and the abdominal operation is without incident However, many women are so greatly relieved that the laparotomy is never performed

5. Acute Intestinal Strangulation.—The distal end of the appendix in Lyons' case was attached to or rather deeply imbedded in the abdominal wall near the umbilicus. Its mesentery was spread out fan-shape, having strong abdominal attachments, just above and to the right of the pubic arch, the appendix and mesentery looking as though they were there attached congenitally. The cecum seemed suspended congenitally in the abdomen, well above the pelvis. In the space between the appendix and the abdominal wall, the intestines were strangulated. They had in all probability gradually entered this space when the patient rested or was sleeping on his abdomen (a position he usually assumed when resting or sleeping), and gradually passed until a large loop of them overhung to the left, and finally filled this space tightly, until strangulation and obstruction were complete.

6. Operative Treatment of Mammary Carcinoma.—Since 1904 in every case of excision of the mamma and axillary enucleation Ruth has divided the two pectorals from the clavicle to the lower border of the axillary space, and the outer part of the muscles are then retracted outward and the inner portion retracted inward, thus at once freely exposing the entire axillary space, which is rapidly and easily cleared from above downward under easy sight at every step. The glands and adipose tissues of the axilla are surrounded by gauze as the enucleation proceeds and they are finally removed with the mamma, going wide of all probable deposit.

The inner or thoracic portion of the pectorals is usually removed, as they can serve no useful purpose and may represent a danger, though small. The distal part of the pectorals which were retracted outward are now brought back and carefully sutured to the thoracic wall above and to the latissimus dorsi and teres major below, directly in contact with the axillary vessels and nerves so as entirely to obliterate all dead space and reduce to an infinitesimal amount the cicatricial tissue which will or can form between the elastic pectoral perimysium and the vessels. The advantages claimed by Ruth for this procedure are not alone the complete obliteration of the dead axillary space, but the reduction of the danger of sepsis by prolonged drainage from a non-collapsible space and the preservation of quite or almost perfect power and range of movement. Again, the distal part of the pectorals used in this procedure has never been known to be secondarily involved in carcinoma and so may be used without a particle of hesitation to cover the axillary vessels, obliterate the axillary dead space and eliminate the compression curve of edema, impaired or destroyed function and torturing pain of 31 per cent. of these unfortunate cases.

22. Blood-Flow in Hands in Heart Diseases.—The smallest flows observed by Stewart in these cases have been associated with marked irregularity of the heart, indicating involvement of the mechanism of the heart beat. In some cases the irregularity was associated with valvular lesions, but in those with the very poorest hand flows there was no evidence that the valves were involved. Three cases were diagnosed as auricular fibrillation, associated with mitral stenosis (and insufficiency). While the flow in all was below normal, it was decidedly greater in one than in the other two, although the patient was much the oldest of the three. His condition was better than that of the other two patients. The ventricle, in spite of its irregular action, was on the whole beating fairly strongly, and was obviously delivering on the average of its beats a fair amount of blood to the periphery. In a case of mitral stenosis and insufficiency and tricuspid insufficiency, in which the heart showed marked arhythmia, in part associated with the respiration (sinus arhythmia), the hand flow was also much below the normal.

Abnormally small flows were seen in a number of cases diagnosed as myocarditis with regular action of the heart, but feeble heart sounds not accompanied by murmurs. In some cases diagnosed as myocarditis without valvular lesion, in which a serious clinical condition had previously existed, very fair hand flows, not much inferior to the normal, were found when the clinical condition had markedly improved. In several cases of mitral insufficiency with good compensation and no signs of impairment of the myocardium, the hand flow was found to be quite up to the normal amount. In one case of mitral stenosis and insufficiency the flow appeared to be even somewhat greater than normal, as if the big, well-compensated heart were discharging more than the usual quantity of blood.

In a case of mitral insufficiency with broken compensation, venous engorgement and edema, but no dyspnea or cyanosis, the hand flow was quite up to the normal. In another case with the same lesions where there was little edema, no shortness of breath except on exertion, and none at the time of examination, the flow was also little if at all inferior to the normal flow, and the reestablishment of compensation was associated with an actual moderate diminution in the hand flow. In a case of mitral insufficiency with physical signs of pericardial effusion a flow not much inferior to the normal was found after the patient had been some time in the hospital and had regained compensation, and when the heart dulness had decidedly diminished. When the patient, two days after leaving the hospital, broke down again and returned with some dyspnea, cough and swelling of the legs, the hand flow was found distinctly below its previous value. In two cases of mitral insufficiency with badly broken compensation, with venous engorgement, edema, cyanosis and dyspnea, the hand flow was much below the normal. In one of these cases a striking diminution occurred a few days before death.

In a case of apparently pure aortic stenosis with perfect compensation, the hand flow was normal in amount. In a case of aortic stenosis and insufficiency with mitral insufficiency, while there were no signs of broken compensation, the hand flow was somewhat below the normal. In a case of aortic insufficiency and stenosis, with badly broken compensation (great dyspnea, pulmonary edema), the hand flow was greatly diminished.

23. Blood-Pressure in Children.—The result of Bass and Wessler's investigation showed that the blood-pressures of children suffering from orthostatic albuminuria differ but little from those of normal children. In spite of the apparent vasomotor insufficiency which many of these children showed, the blood-pressure reactions, both in the upright and recumbent postures and also after exercise, revealed no characteristic anomaly. Nor were they able in any way to correlate the blood-pressure findings with the findings in regard to heart shape and size or pulse-rate. Children with orthostatic albuminuria who showed marked cardiovascular symptoms could not be differentiated by means of blood pressure tests from the remainder of the group

24 **Blood-Transfusion**—Satterlee and Hooker have devised a method of drawing blood from the donor's blood vessel directly into a paraffin receptacle, carrying the blood to the recipient, and injecting it into the recipient's circulation in precisely the same way in which it was obtained from the donor Excepting the air contact of its upper surface while in the receptacle, the blood does not touch anything but paraffin during its passage The paraffin receptacle consists of a thin film of hard paraffin, lining a firm supporting structure The latter comprises a tubulated glass cylinder, closed at the lower end by an asbestos stopper, through which passes a metal cannula The upper end of the cylinder passes directly into an aspirating tube containing an air filter and terminating in a mouth piece The use of this apparatus is described

25 **Condition of Blood in Hemophilia, etc**—Methods are described by Howell for testing the relative amount of prothrombin and antithrombin in the blood The application of these methods to hemophilia shows that the blood in this condition is deficient in prothrombin The antithrombin may be normal or somewhat greater than normal The characteristic peculiarity of hemophilic blood is its markedly delayed time of coagulation This peculiarity is explained by the diminution in amount of the prothrombin which results in a relatively excess of antithrombin The detection of a hemophilic condition of the blood is facilitated by first oxalating the blood and then recalcifying with an optimum amount of calcium Under these conditions the time of clotting exhibited by normal plasma is very constant (nine to twelve minutes) That of hemophilic blood is greatly delayed

In patients suffering from spontaneous thrombosis of the veins Howell found evidence of a diminution in the antithrombin of the blood, the prothrombin being normal It is suggested that this deficiency in antithrombin operates as a favoring, perhaps as a determining, factor in the production of the thrombus In purpura hemorrhagica and other forms of so called purpura, no evidence was found of any variation from normal in either the antithrombin or the prothrombin

28 **Urea Content of Spinal Fluid**—The ninety seven cases studied by Soper and Granat were arranged in four groups (1) cases in which nephritis could be clinically excluded, (2) cases in which death was caused by uremia, (3) cases in which clinical nephritis did not terminate fatally, and (4) pathological conditions with a diagnosis other than uremia, from which, however, nephritis could not be excluded

Of cases belonging to Group 1, there were 56 Thirty three of these cases showed less than 0.05 per cent urea in the spinal fluid, 15 cases 0.05 to 0.06 per cent, 4 cases showed 0.067 per cent, 0.071 per cent, 0.08 per cent and 0.083 per cent, respectively, with no satisfactory explanation, and 4 cases show, respectively, 0.135, 0.179, 0.115 and 0.107 per cent In none of the last 4 was there sufficient grounds to explain the high urea content

In the second group, which comprises 21 cases in which uremia was present, the constant high percentage of urea in the spinal fluid was very striking In 13 cases it was above 0.2 per cent, in 5 cases between 0.1 per cent and 0.2 per cent, and in 3 cases under 0.1 per cent Two of the last 3 were, however, above normal

In Group 3 there were 8 non fatal cases of nephritis The 2 patients in this group who showed marked increase in the spinal fluid urea left the hospital with little if any improvement.

Of the 12 cases tabulated under Group 4 4 presented interesting problems Unfortunately, necropsies could not be obtained in any of them, and it is therefore impossible to exclude nephritis as a complication or indeed the principal cause of death The authors conclude that a spinal fluid urea content higher than 0.2 per cent indicates a severe uremia and a rapidly fatal termination A content between 0.1 per cent and 0.2 per cent means rapidly fatal termination in the majority of cases of nephritis A content between 0.05 per cent and 0.1 per cent does not permit of any definite conclusion either as regards diagnosis or prognosis Such a content is, however, suggestive of severe urea retention and must be taken into consideration in the diagnosis of the condition

30 **Excretory Power of Skin and Kidney**—This study by Plaggemeyer and Marshall has demonstrated that the glands of the skin concentrate urea and ammonia, but that the diastatic activity is less than that in either blood or urine and that uric acid is present in less concentration than in the blood The relative concentrating power of the skin and kidney for urea and ammonia are very different, though in both cases the percentage values are higher than those for blood These facts, in conjunction with the fact that the kidneys show a decided selective action for many dyestuffs, while on the other hand mercury seems to be more readily excreted through the skin, lead Plaggemeyer and Marshall to conclude that, under normal conditions, the skin and kidneys show a distinct selective action The bearing of this on sweat baths as a therapeutic measure in cases of uremia and nephritis is evident The various substances which are producing toxemia in a given case may be among those which the kidney can concentrate, while in sweat they are found in less concentrated form than in the blood stream In the former case, sweating would not be indicated Hence, certain reservations should be made on the efficacy of such procedures as a routine method of treatment

32 Infant Mortality, Ancient and Modern L E Holt New York
33 *Heat and Infant Mortality J W Schereschewsky, Washington D C
34 Medical Supervision of Child between Infancy and School Age H L R Shaw, Albany, N Y

33 **Heat and Infant Mortality.**—It is Schereschewsky's belief that the action of heat as a direct cause in the summer mortality of infants has been greatly underestimated in the last twenty five years In the future much more weight should be given to its influence The lethal action of heat is a function not so much of the maximum and mean temperatures of the external air as of the indoor temperatures, which, in the late summer, may continue to be high in spite of remissions in temperature of the external air The action of dirty and stale milk in causing the death of infants has been given a significance which has overshadowed other factors of equal or greater importance

There is evidence to show that a certain proportion of infant deaths are due to specific infections, in the dissemination of which contact infection and flies doubtless play a part Schereschewsky maintains that future activities for the prevention of infant mortality must concentrate themselves to a greater extent on the question of housing, especially the conditions productive of high indoor temperatures, such as overcrowding, narrow streets and the absence of thorough ventilation Poor housing conditions can be neutralized in part by the proper care of babies in the summer The general public should be educated as to the importance of high indoor temperatures in causing the death of infants, and especially as to measures which prevent babies from suffering from the heat Breast feeding is still regarded as a most, if not the most, important preventive of the summer death of infants

39 Condition of Vasomotor Center in Pneumonia W T Porter and L H Newburgh Boston
40 Study of Cancer S W Little, Rochester, N Y

35 **Mortality of Hereditary Syphilis**—The mortality in 30 syphilitic families has been tabulated by Post In these 30 families there have been 168 pregnancies, of these pregnancies there have been 53 stillbirths and miscarriages, and 44 early deaths—a total of 97 lost, or 57 per cent—71 remain alive Fifty seven per cent of the pregrancies are dead Thirty

eight per cent of the children born alive are dead. Out of the 168 pregnancies, of the 115 children brought living to the world, there remain alive 71; of these 71, 32 have been patients, leaving only 39 presumably healthy. The chief attributed causes in 86 fatal cases in syphilitic families, according to the mothers' accounts, were cholera infantum, 25; marasmus, 27.

38. **Corynebacterium Hodgkini in Lymphatic Leukemia and Hodgkin's Disease.**—A diphtheroid bacillus, similar in its morphological and cultural characteristics to the organism described by Negri and Mieremet, Bunting and Yates, and Billings and Rosenow has been cultivated by Steele from the lymph-nodes of a case of lymphatic leukemia, and one of Hodgkin's disease. Its relationship to these diseases has not been definitely determined, although further studies on this subject are in progress.

55. **Removing Diverticulum of Urinary Bladder.**—In the case cited by Lower, the diverticulum opening was packed with strips of gauze, so that it was converted into a semi-solid tumor. With the fingers within the bladder its upper portion was pulled forward, while by careful dissection the bladder was separated from the peritoneum. With the index finger of the left hand in the diverticulum opening, the bladder was pulled well forward and slightly to the left so that the neck of the diverticulum was brought into view. This was then divided entirely in order to separate the diverticulum from the bladder. The bladder was then pushed laterally underneath and was held away from the diverticulum by means of flexible retractors. As the right ureter was situated at the opening of the diverticulum, it was divided by the circular incision. It was necessary, therefore, to place a catgut suture around the divided ureter to prevent the escape of urine during the remainder of the operation.

The diverticulum which had been converted into a semi-solid tumor by means of the inserted gauze was carefully dissected away from the surrounding structures and removed. The divided ureter was then transplanted into the bladder through the opening made by resecting the diverticulum. A small cigaret drain and a piece of iodoform gauze were inserted outside the bladder into the cavity from which the diverticulum was removed. The fascia was united with chromic catgut and a catheter was placed within the urethra. The patient has made an uninterrupted recovery without any complications whatever.

64 *Two Cases of Removal of Extradural Tumor of Spinal Cord. P. C. Knapp, Boston.
65 Neosalvarsan in Treatment of Parasyphilis of Nervous System. E. D. Fisher, New York.
66 *Anterior Crural Neuritis. C. M. Byrnes, Baltimore.

64. **Extra-Dural Tumor of Spinal Cord.**—Thirty-six cases in which operations have been performed for the relief of tumors of the spinal cord by the advice of the neurologists have been collected by Knapp. In only 11, however, was the growth entirely removed. Eight of these showed more or less marked improvement and only 2 died as a result of the operation,—a mortality of only 18 per cent. In 7 cases a malignant growth was found which could be removed only in part. Even in such hopeless cases 3 were somewhat benefited. In the whole 36 cases 20 were helped by the operation and 12 died, either as a direct result of the operation or from complications following it—an operative mortality of 36 per cent. In view of the hopeless outlook for these cases without operation, Knapp thinks that the experience of neurologists affords further evidence in justification of such operations, even in cases in which the growth cannot be wholly removed.

66. **Anterior Crural Neuritis.**—From a review of the literature Byrnes finds there are, including his personal observations, 136 instances in which the femoral nerve has been the seat of an inflammatory process originating from some internal or medical disorder. The disease has been observed 84 times as a post-partum complication, once as a congenital affection, 8 times as a primary condition, and 3 instances have been referred to which Byrnes has been unable to verify. The remaining 40 cases are distributed among 15 different disorders. In a few instances the inflammation has extended to adjacent nerves, but in each case the most pronounced symptoms have been confined to the femoral distribution.

Of 49 instances of femoral neuritis which have been studied with sufficient care to be instructive, in 33 cases both sides were affected, and in 5 the affected side was not mentioned. In the unilateral cases, the right nerve was involved 17 times; the left 14 times, and in 2 cases the affected side was not stated. Of the bilateral cases, the initial symptoms appeared first on the right side in 5 instances; on the left in 2 cases, and not indicated in 4. If the bilateral cases be regarded as transitory unilateral affections according to the side first affected, and are added to the distinctly unilateral conditions, there are, in a total of 38 cases, 22 instances in which the right side was affected and 16 in which the initial symptoms were on the left side.

In 18 cases the condition was "primary" or "idiopathic." In these 18 cases, the disease was unilateral 14 times; bilateral once, and not stated in 3 instances. Of the 14 unilateral cases, the right side was affected 5 times, the left side 7 times, and unmentioned in 2 cases. In the one bilateral condition the right side was first involved, and if this be added to the 5 distinctly unilateral cases, the two sides are about equally affected. The disease is chiefly met with in middle-aged and elderly people. Of the 33 cases in which sex was indicated, 25 were in males and 8 in females.

The onset of the disease may be acute or subacute. The commonest and earliest symptom is pain in the distribution of the crural nerve or one of its neighboring branches. In the course of a week, or even a month, if the onset be subacute, the pain becomes more persistent, of wider distribution, greater intensity, and of a continuous paroxysmal nature with nocturnal exacerbations. The character, location and extent of the pain are quite distinctive. Except in the mildest cases, there is always some motor disturbance. Weakness and "giving way" of the knee are sommon complaints, and there is some difficulty in raising the leg from the bed when the knee is fixed. There is usually moderate wasting of the muscles on the front of the thigh. The superficial reflexes, epigastric and abdominal, may or may not be altered. Slight electrical changes are usually to be found in the muscles of the affected side. Byrnes believes that there are many instances which have either not been recognized or have been thought to merit no further consideration.

86. **Chronic Intestinal Toxemia.**—*Cornwall's case presents a number of interesting and suggestive points, among which are the following: The patient gave a marked family history of arthritis deformans, and a personal history of a sedentary occupation, of constipation, and of periodical headaches for many years previous to the onset of continuous symptoms. He obtained relief from his continuous and characteristic symptoms by a diet in which the protein derived from animal tissues was scarcely 5 per cent. of the total protein, and in which nearly all of the protein was derived from bread, cereals, milk and cheese; in which the protein ration was kept at a daily average of about 67 gm., and the fuel ration at a daily average of 2,240 calories, from which cane sugar was particularly excluded, and in which was included a considerable amount of the cellulose of green vegetables. He increased both his protein and fuel rations in the months of December, January and February, and diminished them in the other months. He maintained good general health on this diet and gained in weight and had more endurance than when eating his former conventional diet, but was less energetic and slower in his movements than formerly. Since taking this diet the keenness of his sense of taste has increased. Although his continuous symptoms disappeared after taking this diet, and his general condition greatly improved, he continued to have periodic attacks with symptoms suggesting cyclic accumulations of intestinal toxins in the blood or cyclic disturbances of the liver. Symptoms resembling those of these cyclic disturbances could be brought on by eating animal flesh, by unusual physical exertion and by excitement.*

His stools became light yellow in color at the time the cyclic disturbances during the first two years of period of observation, but were nearly normal in color af that period. They were noticeably offensive in odor only the time of the cyclic disturbances, after a laxative. Th were smaller in total quantity while taking the non-putef tive, anticonstipation diet than formerly when taking the c ventional diet. Indicanuria was not a noticeable sympt either at the time of his cyclic disturbances or in the interv between them. A small dose of a saline laxative taken night was usually effective in promptly removing the sym toms of his cyclic disturbances. A larger dose of the sa saline when taken in the morning was less effective. Veg table cathartics were generally less effective than salin though occasionally when the salines failed absolutely abate the toxemic symptoms, which happened periodically, large dose of a vegetable cathartic proved effective for th purpose. Raw cabbage, eaten daily, was of great assistan in overcoming his habitual constipation. His blood-pressu was raised by the cyclic disturbances.

After two years of a non-putrefactive anticonstipation di *the periods between his cyclic disturbances lengthened.*

116. **Infant-Feeding.**—Scientific infant-feeding, Pisek states, consists of doing what is right at the time, for the particular

infant. *It is impossible to state in a book* what shall be done under all conditions, for the conditions are seldom exactly alike in different cases. For example, at one time it may be highly scientific to pasteurize food, and at another time just as scientific to add certain types of bacteria to the food. Here there is no contradiction. Each procedure has its place and in its place is scientific. Out of its place it is unscientific.

125 *Treatment of Acute Endocarditis. J. Phillips, Cleveland.

125. **Treatment of Acute Endocarditis.**—Phillips states emphatically that in the treatment of acute endocarditis the most important thing is rest, both mental and physical. This should often extend over a period of four or six months or even longer. The rest in bed should be absolute, no exertion being done by the patient that can be done for him by others. To counteract the muscular flabbiness that is necessarily an accompaniment of such a long stay in bed, as soon as the temperature is normal, massage should be given daily for a period of thirty minutes, starting first with general rubbing and kneading the muscles and later giving passive and resistive movements. The diet should at first consist largely of milk and cereals, with moderate amount of fluid and alkaline drinks. During convalescence a full diet should be prescribed, especially should milk, eggs and fresh vegetables be liberally given. The bowels should be kept freely open.

The application of cold in the form of an ice-bag is the most useful form of *local treatment. It should never* be applied directly to the skin, but the latter should be covered with a thin piece of flannel and the ice-bag applied over this.

In rheumatic endocarditis, salicylates should be given in doses of 20 grains combined with 30 grains of sodium bicarbonate every hour until the patient is toxic. As a rule, this takes from 180 to 200 grains. After the toxic symptoms, the most common of which is tinnitus aurium, appear, the salicylates are given in doses of from 15 to 20 grains every three or four hours so as to keep the patient on the verge of toxicity until the febrile period has passed. When the sodium bicarbonate is thus combined with salicylate, nausea and vomiting are rarely seen. Salicylates should be continued in moderate doses two days out of every week over an indefinite period of time.

In cases of endocarditis due to causes other than rheumatism, the same general measures of treatment should be followed with the exception of the administration of salicylates, and the disease which is the underlying cause should receive *appropriate treatment.*

If there are signs of failure of the cardiac muscle, among the drugs used to combat this cardiac failure are strychnin, ammonia, camphor or strophanthin, brandy and ether. Where rapid stimulation is needed camphor or strophanthin give the best results. If dyspnea and cyanosis are very troublesome inhalations of oxygen are often of considerable service, especially in children. If the patient suffers a great deal from precordial pain small doses of morphin should be given. Hyperpyrexia is treated by sponge baths as in other conditions. Anemia calls for the administration of iron, occasionally combined with arsenic.

The treatment of malignant endocarditis is that of septicemia—in most cases hopeless. Blood cultures should be taken early and if possible a vaccine prepared and used.

141. **Diagnosis and Treatment of Commoner Thyreopathies.**—This excellent article is so comprehensive that the limited space of this department prohibits a proper abstract.

142. **Cancer Problem.**—Several articles on this subject by Dr. Bloodgood have appeared in The Journal as originals and as abstracts.

143. **South's Greatest Public Health Need.**—A fundamental means "by which government may be put at the service of humanity in safeguarding the health of the nation, the health of its men and its women and its children, as well as their rights in the struggle for existence," is the recording of the vital statistics, the true "bookkeeping of humanity." This is recognized by every practical sanitary and social worker. It is to our shame, says Wilbur, that we have neglected this duty so long; that legislatures and state boards of health have wasted the people's time and money, and frittered away the people's lives through ignorance of the important facts that vital statistics—accurate vital statistics—alone can reveal. When the children's bureau, established for the purpose of protecting the young and charged with the duty of studying infant mortality, is brought to a halt by the absence of the necessary data, it is time to consider why our country should stand in the rear, and not in the van, of national progress. Convinced that the most effective work on behalf of public health that can be done in this country to-day lies in the prevention of infant mortality, the children's bureau is brought to the necessity of appealing for such legislation and such local records as will indicate where and when the babies are born and where and when they die as a preliminary to an intelligent study of the subject.

144. **Vital Statistics.**—Dowling recommends transmission to the legislature of each Southern state, where needed, a petition for the consideration of: (1) The adoption of the model vital statistics law in full. (2) Appropriation of adequate funds to establish an effective system of collection and compilataion of vital statistics and analysis and application of data received. (3) Designation of a date for thirty minutes' discussion before the legislature of reliable vital statistics, the basis of commercial, sanitary and social progress in the South.

146. **The South in Medicine.**—Jones says:

> The chair has preached and taught elevation of standards in our medical schools and in our Association for many years. He will continue to do so. But let us not have our standard so high that the essence and flavor of real good work are squeezed out. Let us not require anything of our prospective students that our faculties cannot conform to themselves. We *read much about the* requirements on the part of the student for entrance, but nothing about

the requirements of the professor who teaches. In all this shakeup of standards begin at the top. Let us standardize our faculties first. We need more standardizing of faculties than we need standardizing of entrance on part of the student. The sauce of the student should be good for the professor. The question, what is the professor's ability to teach? stands in direct relation to the question: What is the student's ability to enter? In raising our standards to any particular point, we say a B.S. or B.A. degree for entrance, let those members of our faculties who have not these degrees promptly resign. Let all those schools throughout the country that have such a lofty standard ask their professors who are not qualified to step down and out.

One of the crying evils of the age is the cramming and crowding too many hours of work in our curricula. We are raising standards, we are raising tuition, which is right. But may I ask how can a student do himself justice as the schedule of lectures now stand?

The Southern Medical Association, in its influence for good, should have the hearty cooperation of every Southern physician. It should be for the physicians, by the physicians and of the physicians. Every Southern medical college worthy of living, though its lot may be hard for a few years, should be dealt with justly.

18 Epidemic Cervical Adenitis. R. D. Rudolf.

13. **Pneumonia.**—Speaking of the diet in pneumonia Barr says that one of the greatest difficulties in private practice is to control the diet; the public has been educated in the belief that great quantities of nourishment and stimulants are necessary, and too frequently the regulation of the diet is left to the nurses and relatives, consequently one frequently finds the abdomen enormously distended with flatus which prevents the free play of the diaphragm. There is usually a paretic condition of the intestinal tract, and any food decomposition is apt to give rise to acute dilatation of the stomach and bowels; when this occurs pituitary extract is the remedy *par excellence.* There is scarcely any anabolic change going on during the febrile stage, so there is no use in troubling the patient with large quantities of nitrogenous food, which are not required and are only apt to form poisonous ptomains. It is a great mistake to worry the patient with much food during the first three or four days of illness, and it should be very gradually increased as the patient seems capable of digesting it. It is not what is put into the patient's stomach, but what he assimilates, that proves of any value.

Barr has found that a good combination consists of an infusion of half a pound of raisins in a quart of hot water with three or four ounces of syrup of glucose, two drams of sodium chlorid and half a dram of the glycerophosphate or lactate of calcium. The patient can drink this *ad libitum.* Milk is an excellent item in the diet, but it is not always easily digested, and consequently it should be well diluted; it should be boiled to get rid of the *bacillus coli* and other organisms. The following is cited to serve an adult in the acute stage for twenty-four hours: About 2 pints of milk, 2 or 3 pints of barley water, whey, or plain water, 6 or 8 ounces of syrup of glucose, 4 or 5 drams of table salt, and 1 dram of the glycerophosphate of calcium. If the syrup of glucose be too sweet or mawkish, a quarter of a pound of sugar of milk can be used. Later on the patient can have peptonized bread and milk or some infants' food, broths, raw eggs, jellies, cocoa or coffee, and a few biscuits. He can have cold water when he likes.

17. **Guaiacol in Pulmonary Tuberculosis.**—Guaiacol is administered by Mayberry in the following mixture, and as a rule he finds it practicable to increase the dose of guaiacol by 2 minims each week until a maximum of 12 to 15 minims is given three times a day: Guaiacol ʒj, spirit. vini rect.℥j, syrupi limonis ℥j, spirit. chloroformi ʒij, aqua ad ℥vj. The dose of this is ℥ss thrice a day.

21. **Postoperative Embolism of Femoral Artery.**—Two weeks after a laryngectomy for cancer Watson's patient was seized by an ascending pallor, loss of sensation and power in the left leg. When seen by Watson six hours after the onset of symptoms no pulse could be felt in the femoral artery below the bifurcation, but iliac pulsation could be felt. The foot and leg up to the knee were cold, pallid and insensitive. Immediate operation was decided on, and Watson exposed the common femoral artery. Pulsation ceased at the bifurcation and Watson decided to open the artery with a view to embolectomy. While raising the artery from the femoral sheath for the purpose of applying a Crile's clamp pulsation suddenly returned in the superficial femoral artery. Watson then exposed the superficial femoral at the lower end of Hunter's canal, as he was unable to satisfy himself that pulsation could be felt there. Watson found that the vessel pulsated as far as the middle of the popliteal space, and closed the wounds. Next day some warmth had returned to the foot, but no pulsation could be felt in the tibial arteries. Gangrene of the foot eventually became established, and a week later Watson amputated the leg through the condyles of the femur.

The artery was completely blocked at the bifurcation of the popliteal by thrombus, which extended down into both tibials. Watson was unable to identify a definite embolus. The patient made a good recovery from the amputation, and is now, nearly two years after the operation of laryngectomy for carcinoma, free from recurrence, and in good health. There is no evidence of vascular disease.

25. **Treatment of Uterine Displacements.**—In the group of cases in which there is a clear indication for pessary treatment Giles includes: retroversion of the uterus following confinement; retroversion occurring in young and nulliparous women, when the symptoms of displacement are of recent origin, and the uterus fails to keep up after simple reposition; retroversion of the gravid uterus in the early months; prolapse of the uterus, with or without cystocele, when the perineum is sufficiently good to hold a ring well up; cystocele with prolapse, with the same proviso as above, that the perineum is sound; all kinds of mobile displacement when the condition of the patient is such as to contra-indicate operation.

Cases in which there is a clear indication for operation are: all cases of backward displacement in which the uterus is fixed by adhesions so that its position cannot be rectified; backward displacement complicated by ovarian tumors or inflammatory disease of the appendages; backward displacement complicated by one or more fibroids admitting of myomectomy; mobile retroversion associated with torn perineum that requires repair; retroversion associated with an atrophic condition of the upper part of the vagina in such a fashion as to render pessaries ineffectual; prolapse of the uterus and vaginal walls, when the perineum is so torn or stretched that no ordinary pessary will keep in place; total procidentia, with the vagina inverted and the uterus lying outside the vulva; particularly when associated with ulceration of the vagina due to friction of the clothes; all cases of displacement when the patient is going to reside abroad in districts where medical assistance is not readily available; all cases of displacement in which a pessary rapidly perishes or becomes rough, or leads to profuse and offensive discharges, or causes inflammation or ulceration of the vaginal walls; cases of displacement in neurotic single women, on whom the concentration of attention on the pelvic organs incidental to the wearing of a pessary, frequent douchings and periodical examinations has a harmful mental and moral effect.

29. **Renal Infantilism.**—Miller and Parsons maintain that a class of symptomatic infantilism secondary to a perversion of renal functions may be recognized ("renal infantilism"). It may occur with organic renal disease; in the cases hitherto reported this type has been due to non-syphilitic chronic interstitial nephritis, whether cardiovascular changes be present or absent. Here the infantilism is likely to be of a severe grade, and death tends to occur during childhood or early adolescence from uremia or pneumonia. It may also occur apart from organic renal disease (diabetes insipidus). This type may be due to inherited syphilis, organic nervous lesions, and the other recognized causes of diabetes insipidus. The infantilism is not of a severe grade, and life may be prolonged. In either type the symptoms, polydipsia, polyuria and retarded development, may be present from birth or may develop during early childhood. Hitherto no case of either type has been materially affected by treatment.

35. **Fatal Illness in Infants and Children.**—In a group of thirteen infants from 2 to 4 months old, nearly all found dead in bed, and all apparently well-developed and nourished, the lungs in eight cases were examined by McNeal and showed marked congestion, bronchitis and bronchopneumonia. This was associated in most cases with hyperplasia, general or partial, of the thymolymphatic system. McNeal believes that these cases of sudden death in infants may therefore be described as cases of fulminant bronchitis and bronchopneumonia, associated with status lymphaticus. The same pathologic grouping was found in all cases examined of a very unusual series of fulminant bronchopneumonia in boys from 10 to 16 years old. The regularity of this association raises the question whether the fulminant nature of the illness in both groups may not have been due in some way to the influence of the morbid constitution usually termed status lymphaticus, the signs of which were unequivocally present in both groups. There is some evidence that fulminant types of other bacterial infections—scarlet fever and diphtheria—are also accompanied by thymolymphatic hyperplasia or status lymphaticus. In the two groups of fulminant pneumonia, thyroid hyperplasia in a marked degree was present in every case examined (eighteen). This thyroid hyperplasia seems to have existed for some time before death. The regular association of thyroid hyperplasia with thymolymphatic hyperplasia, McNeal suggests, may also be a mark of the same abnormal constitution or diathesis.

38. **Fertilization Time in Women.**—Oliver deduces facts to show that fertilization takes place at practically any time during the intermenstrual period, and that the ovum which is fertilized is invariably that belonging to an approaching menstruation, then because the pregnant uterus at or about the fourteenth day after the first menstrual period is missed, is approximately of the same size in every case, it follows that gestation must begin at a definite and fixed time in the human female. This definite and fixed time, Oliver suggests, corresponds most probably with the time when the preparation for menstruation would under ordinary circumstances have been begun, and consequently when a woman aborts about fourteen days after the inhibition of the first menstrual period the aborted product of conception is only about sixteen days old.

40. **Perforation of Duodenal Ulcer.**—The facts of Struthers' case seem to show clearly that a perforation may occur and be closed by adhesion to the liver shortly afterward, and that the adhesion may persist, in spite of the peristalsis associated with digestion, of vomiting, of the patient's getting up, etc., that fluid exudate, which must almost certainly have been present, may be absorbed, and any infective element present may be effectively dealt with by the peritoneum. Ten days after the onset of the illness, the abdomen was opened. The pyloric end of the stomach and the transverse colon were found glued to the liver, with some flakes of lymph along the line of adhesion. There was no fluid exudate present. The liver was easily separated from the stomach by gentle manipulation, and nothing of note was found till the first part of the duodenum was reached. As soon as this was separated, a gush of slightly bile-stained fluid escaped through a round hole, 3 to 4 mm. in diameter, toward the superior aspect of the duodenum, just beyond the pylorus. The fluid was mopped up, and the perforation at once closed and inverted with catgut stitches. There was no collection of fluid present elsewhere in the abdomen as far as could be determined. A posterior gastrojejunostomy was then made and the abdomen closed. The patient made an uneventful recovery.

44. **Perforation of Gastric or Duodenal Ulcer.**—The operation advised by Corner consists of the following steps: (1) Open the abdomen below the umbilicus. Examine the appendix and the pelvic viscera. Place a gauze packing in each loin and in the pelvis and leave them there. Free gas may or may not be seen, but odorless greenish yellow fluid always is. (2) Open the abdomen above the umbilicus, e. g., through the inner part of the right rectus. Find the perforation, mop out any extravasation above and below the liver or round the spleen. Place one end of a gauze "plug" in the perforation to "cork it." Pack a layer or two of gauze plug over the ulcer and wind the rest round a rubber tube which leads out of the wound. (3) Partially close wounds after removing the gauze (draining the pelvis if there is much extravasation). In the convalescence do not withhold morphin, but do not use it heedlessly. At first withhold liquids by mouth except water in ounce doses. It will wash the interior of the stomach. A patient on "rectal saline" is in no great want of food by mouth. In forty-eight hours the drains or "plugs" are removed under an anesthetic and replaced in part. A gastro-enterostomy is not often needed, and no time is wasted in closing the perforation by suture.

50. **Gait in Nervous Disease.**—Abnormalities in gait are all due to loss of well recognized functions of the several parts of the central nervous system, which consists, in brief, of afferent, efferent and coordinating systems. A tabetic has suffered damage to the parts of the posterior columns of the cord, which transmit sensations from muscles and joints, consequently, he depends entirely on sight for his equilibrium, wastes force by throwing the limbs too high and bringing them violently on to the ground, and assists balance by walking on an abnormally wide base. A patient with cerebellar disease cannot control the harmonious action of opposing groups of muscles, although quite conscious of his position, he therefore adopts a wide base, and his gait is reeling because he has to attempt to recover his balance when some ill regulated contraction pulls his center of gravity to one side. If the lesion is unilateral, his inclination is toward the injured side. A hemiplegic patient has rigidity of the whole of one side, and the affected leg is adducted and extended, so that the body must be inclined over to the sound side and the injured limb circumducted. A diplegic patient with the same condition on both sides must do the same with both legs producing the "scissor" gait. A paraplegic patient with less adductor spasm takes short steps, scraping the toes but without crossing the legs. A subject of peripheral neuritis, with paralysis of the dorsiflexors and drooping of the ankle, has to flex the knee and protract the hip so as to lift the drooped foot clear of the ground, thus producing the "steppage" gait. Finally, a patient with paralysis agitans, with rigid limbs and a stooping posture, has to run after his center of gravity with the short steps characteristic of the "festinating" gait. Attention to these considerations enables one in many cases to place the lesion with some accuracy, and Jones claims that the abnormalities in gait, which occur in the different forms of nervous disease, are symptoms of definite diagnostic significance.

53. **Acute Intestinal Obstruction.**—When the sequences of pain, vomiting and relief are present, and accompanied by distention of the stomach, and when the symptoms do not immediately clear up after two or three efficient enemas, given at intervals of an hour or so, especially if the stomach has been washed out at the same time by means of a soft tube, Hartley says, the practitioner will best consult his patient's interests by handing him over to a surgeon without waiting for further signs. If he waits until the abdomen has become distended, he will have enormously increased the difficulties and dangers of operation, and will have correspondingly decreased the chances of his patient. If he still delays until the other orthodox signs and symptoms have developed, namely, until the dry tongue, quick pulse, fecal vomiting, etc., have also become manifest, he will no doubt have made quite certain of his diagnosis, but he may be equally certain that he has almost entirely extinguished the slender chances that remained.

69 *Action on Liver and Kidneys of Stovain Spinal Anesthesia. S. delle Chiaie.
70 *Nascent Formaldehyd in Gynecologic Practice. (De l'imprégnation formolée.) C. Le Masson and J. Marchal.

67. **Ether for Lavage of the Inflamed Peritoneum.**—Phelip and Tartois report sixteen cases in which they poured ether into the peritoneum in treatment of peritonitis from appendicitis in children, and they compare the outcome with a corresponding group of patients not treated with the ether. The impression on the whole is quite favorable. The sedative action of the ether was noticeable and welcome after the operation when child patients are usually more or less agitated. There was less tendency to vomit and the children seemed drowsy and quiet. With circumscribed inflammation they used from 30 to 80 c.c. of ether, pouring it into the pus cavity after its evacuation. When the peritonitis was diffuse, they poured 200 c.c. of the ether into the peritoneal cavity. The cavity was always amply drained. In three of the sixteen cases there were complications on the part of the lungs, fatal in two cases. Is it possible, they ask, that the ether could have affected the lungs? Another child had a cavity in the lung before the operation, and it did not seem to be affected in any way by the ether poured into the peritoneum. (In the control group, without ether, one of the children succumbed to postoperative bronchopneumonia.) Another child died from intestinal hemorrhage several days after the abscess had been evacuated and the small cavity rinsed out with ether. In the three other cases the death was the result of secondary ileus. There is nothing to incriminate the ether in the development of the ileus, the most that can be said is that it failed to ward off the ileus. (The ether method of warding off and treating peritonitis was described in THE JOURNAL, Sept. 27, 1913, p. 1082, and recent experiences with it were reported Jan. 24, 1914, p. 281.)

69. **Action of Stovain Spinal Anesthesia on the Kidneys and Liver.**—At the Naples clinic in charge of de Renzi, Jonnesco's method of high stovain anesthesia was applied in a number of cases, and Delle Chiaie examined conditions in regard to the functioning of the liver and kidneys afterward, to determine if the method was fraught with danger for these organs. The particulars of thirteen gynecologic cases studied in detail are given, and the finding emphasized that while the liver did not seem to be harmfully affected by the rachistovainization, the kidneys, if at all pathologic

beforehand, seemed to be seriously injured. Albuminuria was found constantly in all the patients, but it proved briefly transient in the women whose kidneys were known to be sound, while the albuminuria persisted in an aggravated form in the women with pre-existing albuminuria.

70. **Nascent Formaldehyd for Local Treatment of the Vagina.**—Le Masson and Marchal describe means by which formaldehyd fumes may be generated in the vagina for effectual sterilization by the action of formaldehyd on potassium permanganate crystals. A teaspoonful of each plus one of water is the usual formula. The 40 per cent. formaldehyd solution can be poured on the cystals on a layer of cotton in a stout atomizer bottle, pumping the fumes into the vagina as they are generated in the glass. The simplest method is to pour a few drops of the fluid on the crystals wrapped in a square of gauze and introduce the moistened wad inside a speculum already in place in the vagina. They state that the formaldehyd fumes are neither toxic, caustic nor painful, causing merely a slight smarting sensation.

72 *Results of Treatment of Rectal Cancer. H. Hartmann.
73 Fracture of the Scapula. (Fractures du col chirurgical de l'omoplate.) J. Tanton.

72. **Cancer of the Rectum.**—Hartmann states that the records from eighteen surgical clinics, including his own, show with the low operative technic an immediate mortality of 15.8 per cent. in 1,665 operative cases of rectal cancer; 68 per cent. of the survivors succumbed to recurrence in a few years. This shows that 84 per cent. of the patients with rectal cancer operated on by the direct technic are destined to die within a comparatively short period. The outcome is decidedly better when the low technic was supplemented by a laparotomy, the immediate mortality in 260 cases being only 37 per cent. and the later mortality only 18 per cent. The aim should be, therefore, to perfect the technic for the combined operation, and Hartmann gives a number of suggestions, advising the laparotomy as the first step and closing with colostomy, excluding from the operation patients over 60, the obese, and those with defective kidneys, and removing with the cancer all the linked lymphatics.

77 Wind-Up of Treatment of Gonorrhea. (La fin du traitement de la blenorrhagie.) J. Janet.

75. **Treatment of Tumors in the Bladder by the High Frequency Current.**—Heitz-Boyer credits Beer with great progress in this line, but regards his own spark technic, *étincelage*, as more effectual and more certain than the electrocoagulation method. The spark is applied without direct contact, and he has found it extremely satisfactory in treatment in seventy cases of tumor in the bladder. He gives thirteen illustrations showing the different types of tumor encountered, and the way to reach the pedicle and thus remove the tumor at one stroke, or, by destroying radiating strips in the tumor, to create pedicles which can be severed in turn.

76. **Tests of Kidney Functioning.**—Pirondini's forty-page article reviews the literature on the subject especially when the ureters are not permeable, summarizing the views of leading urologists. If the kidney functioning as a whole is much below par he advises to refrain from removing a diseased kidney, as it is evident that either both kidneys are diseased or that the supposedly sound kidney is insufficient. If the kidney functioning as a whole is still good, the diseased kidney can generally be safely removed. The safety is greater the better the functioning as a whole when one kidney is known to be very seriously diseased. Intravesical segregation of the urine from each kidney is not a reliable means of investigation as a rule, unless the findings are clear and constant on several examinations. Chromocystoscopy may prove useful, permitting a guess at the functioning of the kidneys, and it sometimes aids in permitting catheterization of the ureters. If none of the above are practicable, the only way to obtain an insight into kidney functioning is by direct inspection of the supposedly sound kidney and the upper portion of its ureter or ureterostomy on this side or catheterization of the ureter after opening the bladder. The latter seems preferable to exploratory incision on both sides to expose both kidneys in turn. This does not permit examination of the urine.

83 *Osteomalacia. S. Bonnamour and A. Badolle.
84 Action of Theobromin and Sodium Salicylate on Edema. A. Kakowski.

83. **Osteomalacia.**—Bonnamour and Badolle conclude from their extensive research that osteomalacia is not due to any one single cause, but may be regarded as a syndrome originating either from infection, from disturbances in internal secretion, or from abnormalities of nutrition. The nervous system may reenforce either one of these original causes, either reflexly or through the vascular system, but it does not seem in itself to cause osteomalacia. The most evident and most incontestable result of osteomalacia is the decalcification of the bones, the loss of lime being manifested in the abnormally large proportions of lime found in the blood, urine and stools. Determination of the proportion of lime in the blood is thus useful both for diagnosis and prognosis.

94 Eosinophil Leukocytes in Inflammatory Infiltrates, Especially with Uterine Cancer. E. Weishaupt.
95 Hypophysis Extract in Obstetrics. (Pituitrin in der Geburtshilfe.) H. Oppenheimer.

87. **Action of Hypophysis Extract from Castrated Animals.**—Kleemann's experiments with hypophysis extract from various animals after removal of the ovaries or testicles, or merely of the corpora lutea, demonstrated that the effect was the same with six of the normal and the castrated animals, but that the effect differed materially when the extract was

taken from the hypophysis of a gravid animal. The extract obtained from gravid animals sometimes had a dilating and sometimes a constricting action on the vessels. He suggests that the contradictory experiences with hypophysis extract that have been reported may be explained by the fact that the extract in some cases came from an animal that was or had recently been gravid.

88. **Appendicitis during Pregnancy.**—Füth emphasizes the liability to errors in the diagnosis of appendicitis during the later months of pregnancy as the cecum is lifted up by the uterus so that the appendix is found high above its normal location. The conditions with pregnancy also favor development of more serious complications as he shows by a recent case in which pus flooded the field at the appendicectomy and the dead five months' fetus had to be removed by vaginal cesarean section.

89. **Amenorrhea and Tuberculosis.**—Friedrich found amenorrhea in 45 per cent. of forty-two women in the first stage of pulmonary tuberculosis; in 64 per cent. of ninety in the second stage and in 85 per cent. of sixty-eight in the third stage. She also reports that the lipoid content of the blood was found abnormally high in gravid rabbits, and still higher proportionally in pregnant women. She suggests that this lipoidemia may explain the frequent aggravation of tuberculosis by a pregnancy, and that it may possibly serve in the diagnosis of pregnancy.

91. **Kidney Complications in Pregnancy.**—Jaschke states that kidney affections were responsible for 27 per cent. of the mortality among the women with heart disease as reported from various maternities (31 of the 114 deaths). Fellner has also recently reported the fatal outcome of the pregnancy in 32 per cent. of his patients with heart disease plus nephritis. Valvular affections predominated. Jaschke regards it as immaterial whether the kidney trouble is recent or of long standing. If the kidney affection in a pregnant woman with heart trouble is accompanied by high blood-pressure, the pregnancy should be interrupted without delaying too long, as this is generally the only chance of saving the patient.

93. **Pregnancy Pyelitis.**—Weibel states that eighteen of the twenty-six women with pregnancy pyelitis proceeded to term with living children; five others had living children born prematurely; one woman aborted, and one developed eclampsia. All the women recovered, and he ascribes these comparatively good results to the routine treatment of direct medication of the kidney pelvis, refraining from operative measures. In 100 normal pregnant women he found the ureters more or less obstructed in 47 per cent., and predominantly on the right side.

103 *Spinal Anomalies as Predisposing to Pulmonary Tuberculosis. (Bedeutung von Wirbelsäulenanomalien.) N. Küchenhoff.

96. **Plane Projection of the Thorax.**—Sandberg says that the general practitioner is too apt to neglect the axilla in examining the thorax. To combat this he has worked out for clinical records a plane projection of the upper part of the trunk, front and back, divided into six vertical fields, two of which represent the axillae.

97. **Masked Tuberculosis.**—Nohl gives the details of eight cases in which the final course showed that the pains and aches must have been the work of attenuated tubercle bacilli, a tuberculous rheumatism. He agrees with Poncet that the first thing in a case of rheumatism is to exclude tuberculosis. A rheumatic affection with a dragging course, tendency to ankylosis and lack of response to salicylates is suspicious of tuberculosis, especially when the general health suffers more than can be explained by any local process that can be discovered. It is better to err on the side of treating true rheumatism for tuberculosis than to neglect the measures necessary to combat the tuberculosis. The tuberculous rheumatism may manifest itself in various ways, from all forms of arthralgia up to the severest type of bony ankylosis. The tuberculous joint affection may subside and some visceral or pulmonary lesion then become manifest, or the joint trouble may come on as a visceral or pulmonary tuberculous process becomes inactive.

Nohl describes in detail nine cases which illustrate different types; the patients were between 17 and 30 except one woman of 35. The first symptom in one case was dysmenorrhea at times for a year and a half with pains in the joints; then acute peritonitis developed with severe paroxysmal pains but gradually subsided, leaving subfebrile temperature and constipation. A brief attack of pleurisy with effusion followed. The patient was treated as for tuberculosis, and she has been in good health for over two years now except for occasional rheumatic pains at various points. The trouble began in the second case with the syndrome of gout or subacute articular rheumatism, with severe pains in muscles and nerves, moderate fever, paroxysmal coughing, foamy sputum, râles, etc., all subsiding and returning at intervals. Then all these symptoms subsided and attacks of bronchitis followed, with continuous slight fever and at night symptoms of angina pectoris without weakness of the heart, and finally peritonitis with effusion. No tubercle bacilli were found at any time and inoculation of animals was negative, although years before the patient had had an apical tuberculous affection which subsided to a clinical cure under a course of tuberculin treatment.

98. **Phagocytosis of Tubercle Bacilli.**—Kirchenstein concludes from the comprehensive research which he reports that the essential causes of phagocytosis are of electrochemical nature.

99. **Scarification Technic for Tuberculin Treatment for Tuberculosis.**—Dübi analyzes twenty-five cases of pulmonary tuberculosis with tuberculin treatment by Sahli's method of multiple scarifications. To render the technic more uniform, he used a set of twenty-five needles mounted in a stamp, all pricking the skin at once. A drop of tuberculin in the desired dilution is dropped on the group of minute holes thus made, and a transient reaction follows. The true tuberculin reaction does not develop for about half a day or possibly not until after one or two days. By this method the area to which the tuberculin is applied is much larger than with other technics, and a weaker concentration can be used. This reduces to the minimum the general reaction while the absorption is more complete. He says that it is thus possible with effectual therapeutic doses to avoid any febrile reaction at any time through the long course of treatment, even in patients who always react with fever to corresponding or even smaller doses by the subcutaneous route.

100. **Alcohol and Tuberculosis.**—Holitscher sent out 7,300 question blanks for physicians connected with tuberculosis sanatoriums to fill out, one for each patient, giving the details in regard to the tuberculosis and drinking of spirituous liquors in the individual case and in the recent and remote family history. He was much disappointed that English physicians ignored his request, only Sweden, Norway and Hungary cooperated in the research, but he received a total of 3,000 filled-out blanks. The data show that the tuberculous do not become hard drinkers as a rule, but that persons addicted to alcohol are particularly liable to contract tuberculosis.

103. **Anomalies of the Spine Predisposing to Pulmonary Disease.**—Küchenhoff declares that too little regard is paid to the shape of the spine as providing a mechanical predisposition to apical lesions. When the upper part of the spine curves forward, the spinous processes project downward and encroach on the apex space, so that even slight kyphosis of the upper spine interferes materially with the circulation in and expansion of the apices. He gives two portraits of "round-shouldered" men as types of the anomaly in question, emphasizing that while tuberculous processes elsewhere in the lung

usually display a tendency to heal, those in the apex, handicapped by these mechanical conditions for which the spine is responsible, are unable to oppose adequate resistance to the infection

104 **Splenectomy for Pernicious Anemia.**—Eppinger quotes five other clinicians who have reported constantly favorable results from removal of the spleen in treatment of pernicious anemia He here discusses the mechanism of the benefit derived, his research indicating that the blood vessels in the spleen are modified in a peculiar way which permits the red corpuscles to escape into the pulpa, where they are destroyed The normal way through the capillaries seemed to be obstructed in the seven spleens he has removed for pernicious anemia When the red corpuscles escape into the pulpa and thus come in contact with connective tissue and die off, the conditions are much like those with hemorrhage from an artery, removing the spleen puts an end to the process, and it is possible also that merely ligating the splenic artery would answer the same purpose This should be reserved for cases in which there are objections to removing the spleen He calls attention further to the possible occurrence of 'blood lymph nodes," *Hamolymphdrusen*, in cases of pernicious anemia, they seem to be of a structure analogous to that of the spleen, and seem to be able to compensate for the lack of the spleen They are found in many animals, and he has noticed them in profusion in cases of pernicious anemia When benefit does not follow splenectomy, it is more than probable that these blood lymph nodes are carrying on the pernicious activity of the spleen Special attention should be paid to them in all cases of pernicious anemia, but the possibility of their presence, he reiterates, should not bring discredit on splenectomy as the most important measure in treatment of pernicious anemia

106 **The Gall-Bladder and the Chemistry of the Stomach**—Boss gives the stomach findings in nine cases from one to five years after removal of the gall bladder, and also in eleven cases in which the chemistry of the stomach was examined before the gall bladder was removed The findings fail to confirm the assumption that conditions in the gall bladder and its outlet influence secretion in the stomach, there was hyperacidity in some and hypoacidity in others In still others gastric secretion was entirely normal although the biliary apparatus was totally obstructed

110 **Effect of Excessive Carbohydrate Diet on Metabolism.**—Many experiments have been performed to show the effect of large amounts of carbohydrates given at one time, and of a long continued excess of carbohydrates given with albuminous food But Grafe undertook the giving of large amounts of carbohydrates without albumin in order to determine the part played by nitrogenous food in forming reserve material and especially in the transformation of carbohydrates into fat The experiments were carried out on pigs, dogs and human beings There was no increase in weight and in several cases there was a decrease This seemed to be explained by an increased output of water and increased oxidation The reserve material laid up was almost entirely dry matter The addition of albumin to the carbohydrate diet immediately changed the negative water balance into a decidedly positive one The intensity of oxidation remained about the same, but in dogs the formation of fat from sugar seemed to be increased Tables are given showing in detail the weight, nitrogen balance, water balance and heat production in the different experiments

112 **Effect of Carbohydrates on Metabolism in Fever**—It has long been known that there is an extensive loss of nitrogen in fever Pfannmuller undertook to find out to what extent this could be reduced by the feeding of carbohydrates In a healthy man with no fever he found that by giving 500 gm sugar the nitrogen output was reduced approximately 10 per cent He describes, giving tables and temperature charts, three febrile cases in which he fed sugar and rice, as compared with a healthy control He found that with this he could not only compensate for the excessive nitrogen output but that it was actually reduced to lower figures than in the healthy individuals

115 **Asphyxia**—Grober says that fortunately in this condition the term "asphyxia," which means 'not beating" is a misnomer as the main trouble is with the lungs which are unable to get enough air to work on The heart may keep on beating faintly for a long time The radial pulse may be imperceptible while a pulse can still be felt in the carotid He discusses the asphyxia from hanging drowning, excessive hemorrhage, intoxication and breathing of suffocating gases After removing the cause of the asphyxia, the heart must be sustained, and the best means for this is by subcutaneous injection of camphor, injecting 1 c c at two, three or four different points of the body

In severe asphyxia it is better not to attempt to give anything by the mouth If the circulation is almost at a standstill, the camphor will not be absorbed, but by starting up the circulation by other means there will be this available reserve of stimulant for the heart Artificial respiration should then be started

The apparently drowned must have mud and slime wiped out of the mouth, prying open the jaws if necessary for the purpose When the patient has been buried under sand or dirt, this clearing out of the mouth is particularly important *Tracheotomy may be necessary* and this can be done on the unconscious patient without general anesthesia and, owing to the weakness of the heart, without fear of much hemorrhage Saliva, mucus and foreign particles are liable to accumulate at the entrance to the air passages during the course of artificial respiration, and such accumulations should be wiped out at intervals The natural respiration can be promoted and expiration increased by rhythmic pressure on the lower ribs or upper abdomen The elasticity of the chest in the young provides sufficient inspiration when the pressure is relaxed but this is not sufficient for the elderly. It is useful at intervals, during systematic artificial respiration to rest the workers Grober has also found useful sometimes a method of working on the diaphragm by raising the seat so that the pubis forms the highest point of the body, both legs are then lifted together, flexed at knee and hip, and pressed against the abdomen. This forces the relaxed abdominal walls and the intestines upward and against the diaphragm which bulges upward also and the air is thus expelled from the lungs. Drawing the legs down again and spreading them slightly expands the lungs again in turn.

There is great loss of body heat during asphyxia so that provision must be made for warmth, hot bottles, hot stones and blankets, supplemented by rubbing the extremities to aid the circulation, flexing rhythmically the knees and elbows to reduce the stagnation of blood. If the heart action grows weaker the pauses in the artificial respiration must be utilized to give heart stimulants. The last resort is massage of the heart, tapping with the palm or striking with the fist the chest wall over the heart, once a second. When this failed, some surgeons have reported success from direct massage of the heart, opening the abdomen for the purpose. There is danger of collapse later, when the patient is apparently out of danger, consequently he must be kept under close supervision, even after mild asphyxia.

116. **Treatment of Dilatation of the Esophagus.**—The main principles of Starck's treatment of patients with diverticulum or dilatation of the esophagus were summarized from the first part of his article, abstracted in these columns January 31.

124. **Diagnosis of Kidney Lesions of Occult Tonsillitic Origin.**—Pollitzer recommends testing the urine for chondroitic acid as well as for albumin in case of kidney trouble in the young. The chondroitic acid, he says, seems to be a sign that the kidneys are suffering from the effects of infection. This is almost always traceable to the tonsils, and by systematic massage of the tonsils or by tonsillectomy the source of the trouble can be removed. He called attention recently to the fact that the urine in young persons with orthostatic albuminuria and in certain other conditions in which the urine is clinically free from albumin, becomes intensely turbid when treated with serum albumin in an acetic acid solution. This reaction is due to the presence of chondroitic acid. He gives an illustrated description of the simple technic for the test, and its mechanism.

132. **Misleading Pains in Pleurisy.**—In the course of two recent years seven patients were sent to Gerhardt's surgical service to be operated on for appendicitis, when the trouble proved to be merely abdominal pains ushering in pneumonia. In four other cases the pains were in the shoulder, and one patient had been treated for a supposed shoulder-joint-trouble. In all four cases the friction sounds of pleurisy were evident but only over the lowest part of the inferior lobe. In one case there was an infarct in the lower lobe but the pleurisy caused no effusion and the pains in the shoulder subsided in about twelve hours. In two of the patients the pleuritis was secondary to pneumonia of the inferior lobe, and the pains in the shoulder lasted only for twenty-four hours. The fourth patient had chronic pleurisy without effusion and the pains in the shoulder kept up for two weeks. This isolated pain in the shoulder with diaphragmatic pleurisy is evidently connected with an irritable condition of the sensory fibers of the phrenic nerve. Its practical importance lies in the necessity for differentiating the primary pleuritis when pain in the shoulder suggests a joint process. Tenderness of the nerve may aid; the location and spread of the pain are like those with neuralgia of the phrenic nerve except that the nerve trunk is usually involved in the latter while with the pleurisy the terminals are the seat of the trouble.

133. **Specific Action of the Abderhalden Defensive Ferments.**—Mayer states that his experience in 110 neurologic and psychiatric cases has confirmed the specific nature of the enzymes involved and the results of the experimental research he reports corroborate this further. They also show that for clinical diagnosis, organs from another species may be utilized. He says that the contradictory results reported by some writers may be due to the fact that they did not give the ferments time to develop. He allowed four, five and seven days, and found then an absolute organ specificity in the rabbits.

134. **Electric Treatment of Obesity.**—Roemheld has treated twenty obese patients with electric exercising of the muscles, but did not witness any reduction in weight greater than what was realized with ordinary dietetic restrictions without the "bergonizing." The main thing in treatment of obesity is and must be regulation of the diet, and Bergonié himself only regards the electric passive exercise as one factor in the treatment of obesity.

On the other hand, Roemheld thinks that the electric passive exercise is destined to prove of great importance as a means of exercising the muscles in heart disease. With careful application, the method does not increase the blood-pressure or show any other deleterious action, while it is an excellent means of exercising the muscles. It is useful for the same reasons in cases of disturbance in the peripheral circulation with reduced tonus of the vessel. It is also a practical and efficient means to strengthen and give tone to the abdominal and pelvic muscles after a childbirth, as already mentioned in these columns, Nov. 29, 1913, p. 2024.

139 *Appendicitis in the Elderly. J. Philipowicz.
140 *Sagging Chest. (Thoraxsenkung.) L. Hofbauer.

139. **Appendicitis after Fifty.**—Among 1,080 patients with appendicitis at von Eiselsberg's clinic since 1905, twenty-nine of the patients were between 51 and 72. The inflamed appendix was found in a hernia more frequently among the elderly, but incarceration of the appendix causes less disturbance than when a loop of intestine is involved. In four cases the insidious onset with extreme emaciation and signs of obstruction of the intestine in three cases and even blood-stained stools in one instance, suggested cancer in the large intestine, but the whole trouble subsided after removal of the chronically inflamed appendix. In the fourth case the only symptoms were from the stomach; the insidious course, emaciation, tenderness in the epigastrium, hyperacidity and lactic acid in the stomach content, and dubious roentgenoscopic findings pointed to gastric cancer, but all disturbances ceased after appendicectomy, the chronic appendicitis having entailed adhesions between the ascending colon and the duodenum.

140. ***Attitude of the Chest Predisposing to Disease.***—Much attention has been attracted to Czerny's recent statement that he has scarcely ever found apical tuberculosis in narrow-chested children while, on the contrary, he has found it common in children with unusually full, expanded chests. The chest in the latter group is inflated to the utmost and keeps inflated, the air not being adequately expelled from it. Hofbauer's experience has confirmed this and also the predisposition to apical processes induced by the lack of expiration of the air. Health depends on elastic filling and emptying of the air

passages, thus providing for proper circulation of air, blood and lymph. When the apex is kept permanently still, the conditions favor disease, regardless of whether the immobilization is from persisting expansion or from persisting lack of air. He calls attention to the harm that may be done by exercises in deep breathing without providing for thorough emptying of the lungs. Laymen are fond of these deep-breathing exercises, but they do not realize the necessity of equally deep expiration. As the exercises are frequently done, they afford an actual predisposition to tuberculosis rather than the reverse.

The defective participation of the muscles in the act of expiration has an injurious influence on the abdomen also. When the front of the chest sags, the abdominal walls below sag with it and conditions favoring enteroptosis develop. By training the muscles of expiration, the abdominal wall regains its elasticity and the normal play of the elastic forces throughout is restored. As Hofbauer expresses it, correction of the dynamics restores normal statics in the thorax.

144 Boy of 13 Never Learned to Swallow Solid Food. (Nährschaden durch psychogene Perseveranz auf Milchkost.) T. Goett.

143. **Stomach Digestion in Infants.**—Davidsohn describes in detail his methods of examining the contents of the infant's stomach, and calls attention to the fact that the reaction is much less strongly acid than in the normal adult stomach. This weakly acid reaction is the one most favorable for coagulation, for lipolysis and casein digestion. Digestion takes place in two stages, first coagulation and then digestion of the fat. The maximum of coagulation is reached about forty-five minutes after ingestion of the milk. Contrary to the condition in adults, there is no backward flow of pancreatic juice into the infant's stomach. But there is a lipase secreted in the stomach itself which has marked fat-splitting properties. The higher the fat-content of the milk the longer it stays in the stomach.

149. **Cork Paper for Protection of Thiersch Flaps.**—The extremely thin sheets of cork paper such as are used for the tips of cigarettes have proved of great assistance in the management of Thiersch flaps at de Quervain's clinic during the last six years. The sheets of cork tissue are 10 by 15 cm. in size, and 1/100 or 1/10 mm. thick; they are porous, flexible, and can be sterilized with the dressings in steam. They can be fitted to almost any surface and the dressings do not stick to them so much as to some substances. The cork paper is applied at once after the grafts are in place, and it is left as a rule until it is spontaneously cast off. The dressings above it can be changed as desired but they are generally left undisturbed for six days.

150. **Operative Treatment of Movable Cecum.** — Francke shortens an abnormally long cecum by running three or four fine silk threads lengthwise of the gut over a space of about 8 or 10 cm., taking each stitch about 1 cm. long, at intervals of the same length. Each silk thread is then tied separately. This puckers up the gut, folding it in and out like a harmonica, and shortens its length by one-half as desired, curing all tendency to sagging or torsion, while leaving the gut still freely movable in its place.

157 Radiotherapy of Cancer. Flatau.
158 Acromegaly and Ovarian Therapy. H. Bab.

156. **Fascia Sling for Total Prolapse of Genital Organs.**—Schubert says that the usual methods for correction of prolapse do not go to the root of the trouble, that is, the relaxed and sagging condition of the fascia supports of the uterus. This insufficiency of the fascia supports is not remedied by the usual fixation of the organs or shortening of ligaments. He has applied in six cases a method by which two strips of fascia taken from the abdominal wall are passed around the uterus and across the cervix and crossed again over the symphysis, suturing them along their course and drawing up tissue over them to leave no recess at any point into which a loop of bowel might slip. He operates through a transverse incision. The method has been applied to date only where there was no further chance of a pregnancy. He proposes where the uterus is still functionally capable to modify the technic, making the fascia sling by drawing the fascia strip across the pelvic inlet and suturing it to the rear of the ligament. The fascia lata could also be utilized.

162 Cultivation of Pathogenic Protozoa. E. Bertarelli.

161. **Diphtheria Simulating Glandular Fever.**—Galli remarks that while the course of Pfeiffer's disease is generally mild yet occasionally it assumes a graver form, the fever persisting long past the usual four or five days and the system showing the effects of extreme intoxication. This syndrome, he is convinced, is the work of diphtheria bacilli. They do not settle in the throat as usual but start trouble in the cervical lymph-nodes. He reports seven cases of this type, the onset stormy, the toxic action increasing up to the fifteenth day, with prostration, but no signs of diphtheric false membranes or other characteristic findings in the throat. Smears from the nasopharynx disclosed bacilli resembling diphtheria bacilli, and the children began to improve at once on injection of antitoxin. He says the syndrome might well be called follicular diphtheria. The swollen and painful glands were always those back of the sternocleidomastoid muscle in each case; none elsewhere seemed to be involved in the process.

169 *Strangulated Hernia, 164 Cases G Egidi Commenced No 22
170 Vaccine Therapy in Typhoid A Blocca

169 **Strangulated Hernia.**—Operative treatment was applied in all but one of the 164 cases reviewed, the communication embracing fourteen years' work in R Bastianelli's service at Rome Twenty eight of the operative cases terminated fatally, and the details are tabulated in these fatal cases for comparison They show that even in this enlightened age many persons let an incarcerated hernia progress to the stage of gangrene before seeking a physician, in only five of the eleven patients who died within a few hours after the operation was the intestine found in a condition which would have permitted its retention The outcome depends more on the general condition than on the condition of the intestine, the disturbances from arrested bowel functioning had brought some of the patients to the brink of the grave even when the bowel itself was not irremediably injured The material reviewed teaches further that it is better to resect the injured tract rather than to try to get along without resection by making an artificial anus in the small intestine Patients operated on in this way died from inanition

The prognosis of resection depends on both the general condition and the condition of the bowel, and these do not necessarily parallel each other by any means When resection can be done with the patient's general condition still good, the outlook is comparatively favorable In one case it semed safe to reduce the hernia and the loop retained its vitality unimpaired but adhesions developed rapidly, kinking the gut and compelling resection the third day, which the patient was unable to survive One patient succumbed to chloroform intoxication, manifested in jaundice and acute nephritis, another to cerebral embolism, and five to complications on the part of the respiratory organs In this last group resection had been done in only one instance, in the others the intervention had been of the mildest character The anesthesia had been by the spinal route in two in this group The general anesthesia certainly contributed to the catastrophe in the others A simple technic is advocated which can be done under local anesthesia and which has worked well in the three cases in which Egidi has applied it The gangrenous stretch is tied off with a ligature at each end and is cut out with the actual cautery Each stump is then turned inward and sutured and the gut beyond is brought together for an anastomosis This technic is particularly adapted for a femoral hernia In conclusion Egidi reiterates that he is convinced that local anesthesia answers all purposes for operating on a strangulated hernia, while general anesthesia is particularly dangerous when the system has been seriously poisoned by the effects of the obstruction in the bowel

175 Hemo angioma of the Mammary Gland G Marangoni
176 Primary Tumors of the Serous Bursae G Bolognesi

174 **Involvement of Liver with Cancer of Kidney**—When the tumor is in the upper part of the kidney it pushes the liver up as it develops, causing the liver to pivot on its transverse axis The natural consequence is that the symptoms are generally all from the liver In the first of the two typical cases of the kind reported by Saviozzi there was no hematuria or disturbance in urination An exploratory laparotomy revealed the inoperable cancer, the kidney projecting like an appendix from the liver The patient died in a few hours The first vague disturbance in the abdomen had been noted only six months before In the second case the patient was a man of 24 and the interval had been less than two months after the first symptoms, merely pain at times in the liver region Then fever and chills followed The diagnosis of echinococcus cyst of the liver seemed certain until hematuria drew attention to the kidney On account of the resemblance to the first case the true condition was then differentiated, and the operation confirmed it in every particular Küster has reported a similar case in which the patient died from embolism in the pulmonary artery before the operation had been concluded, and this occurred likewise in the case under discussion The cases teach that liver symptoms in a case of primary kidney cancer seem to show that the growth is practically beyond operative relief The pathologic anatomic details are shown in five large plates, two of them colored

ORIGIN AND PRESENT STATUS OF THE EMETIN TREATMENT OF AMEBIC DYSENTERY [*]

EDWARD B. VEDDER, M.D.
Captain, Medical Corps, United States Army
WASHINGTON, D. C.

Amebic dysentery is known to be fairly common in certain parts of the United States, and as a matter of fact is more generally distributed and more frequent than is usually supposed. The treatment of this disease, in the past, has been rather unsatisfactory; but within the last two years a new treatment, namely, the hypodermic injection of the soluble salts of emetin (alkaloid), has been introduced. Since the literature bearing on this work is scattered throughout the medical journals of the world, and much of it is rather inaccessible, it is thought that a discussion of this subject will prove of interest.

THE ORIGIN OF THE EMETIN TREATMENT

Large doses of ipecacuanha have been used for many years in the treatment of dysentery, particularly by the English practitioners in India. Even before this use of the drug, Pelletier, in 1817, described an alkaloid in ipecacuanha which he called emetin. Later researches have shown that this alkaloid of Pelletier was, in reality, a mixture of three alkaloids, emetin, cephaelin and psychotrin.

Until very recent years these alkaloids have remained pharmacologic curiosities, and were not generally used in medicine. Attempts to use emetin have naturally been made from time to time. Thus Captain Douglas,[1] I. M. S., says: "It would seem that the use of emetin in dysentery is not new to therapeutics, for in 1817 Magendie and Pelletier recommended its use and L. Bardsley in 1829 obtained good results in dysentery and chronic diarrhea. That this very effectual remedy passed from the ken of medicine was most probably due to the fact that the differences between amebic and bacillary dysentery were not diagnosed." This is also probably the explanation of the failure of Walsh,[2] who used emetin mercuric iodid without result in the treatment of acute dysentery. As Walsh himself said, "it (emetin) is not proved to be much better than preparations of *Wrightia antidysenterica*, and I do not claim any preeminence for it, nor do I recommend it above other drugs. It is not even proved to be better than other drugs, which are not supposed to have any 'specific' action on dysenteric conditions."

Walsh did not state whether or not any of his cases were amebic in origin, but since he was treating acute dysentery, it is probable that the majority of his cases were bacillary dysentery. Moreover, he administered the mercuric iodid salt of emetin, which was probably not a particularly favorable preparation. These and other attempts to use emetin proved unsuccessful.

Moreover, there was a great divergence of opinion as to the value of the ipecac treatment of dysentery. Many authors lauded it as a specific, but, on the other hand, equally eminent authorities failed to obtain any results whatever from this treatment, and condemned it as unscientific and worthless.

It seemed apparent that there must have been some good reasons why authorities should, after careful trial of ipecac, arrive at conclusions diametrically opposed, and it seemed probable that this discrepancy might have resulted, both because different preparations of ipecac varied considerably in their action, and because some of the investigators had used ipecac indiscriminately in all dysenteries, whether bacillary, amebic or due to some other cause.

Experiments[3] were therefore undertaken in 1910 to determine whether or not ipecac had any decided action against either dysentery bacilli or amebas, and if such action were present, to what constituents of the ipecac this action was due.

The results of these experiments were suggestive. In brief, it was demonstrated that ipecac possessed no specific bactericidal effect against *Bacillus dysenteriae*, but that it was a powerful amebacide, the weakest preparation used killing amebas in a dilution of 1 : 10,000. It was further shown that emetin was exceedingly active, killing amebas in dilutions of 1 : 100,000, that deemetized ipecac was relatively quite inert, and that different preparations of ipecac on the market varied greatly in their alkaloidal content and amebacidal action. It was therefore suggested that the amebacidal action of any given specimen of ipecac was directly dependent on the proportion of emetin contained.

In a later publication[4] these results were reaffirmed, and it was pointed out that the greater part of the emetic action of ipecac is not due to emetin but to cephaelin, and that if emetin were amebacidal without being especially active as an emetic, we should have at our command the ideal drug for use in amebic dysentery, a drug that might prove as satisfactory as is quinin in malaria. The hope was expressed that other workers would become

interested in the problem and verify the observations. This hope was already in the process of being realized. Lyons,[5] working independently on the same problem, had failed to find that ipecac had any amebacidal effect on amebas *in vitro,* but stated that the alkaloidal content of his preparation of ipecac was unknown. One specimen which remained was assayed and found to contain only one-fifth of the total alkaloids required by the U. S. Pharmacopeia.

Wherry's conclusion,[6] as the result of similar observations, was: "Emetin in 1 : 20,000, 1 : 100,000 and 1 : 200,000 dilutions killed the amebas in one of the five series of experiments after twenty-three hours' exposure at from 36 to 38 C. (from 96.8 to 100.4 F.). None of the dilutions was amebacidal in an hour. It seems fair to presume that when amebacidal action was manifested, the emetin acted on the trophozoites alone, and that failure to kill may be attributed to the presence of cysts."

These experiments were all performed with free-living amebas which could be cultivated. Since the parasitic amebas are far less resistant to unfavorable agencies, it was reasonable to suppose that these also would be destroyed by emetin. Rogers was attracted by Vedder's results and tested the action of emetin solutions on *Entamoeba histolytica* in dysenteric stools.[7] He found that motility ceased promptly and that destruction of the amebas rapidly followed. These experiments, however, were comparatively unimportant. I had, myself, made a few similar observations, but had not considered them of particular significance, because the parasitic amebas soon lose their motility and disintegrate rapidly even when kept in a stool or liver-pus under the most favorable circumstances, and also because, as is now generally admitted, the pathogenic *Entamoeba histolytica* has never been cultivated, and it was, of course, impossible to prove whether the amebas apparently killed by emetin were really dead or not.

The credit, however, for having first utilized the experimental results in the treatment of dysentery belongs to Rogers. He had long advocated the use of ipecac in amebic disease, and in 1907 demonstrated that the same drug would rapidly cure an amebic hepatitis in the presuppurative stage, and thus prevent the formation of amebic liver abscess. Having been convinced of the action of emetin on amebas *in vitro,* Rogers decided to use emetin hypodermically, and in June, 1912, he reported[7] two cases of severe amebic dysentery and one case of acute hepatitis which were rapidly cured as the result of this treatment.

In August, 1912, Rogers published further experiences with emetin in amebic disease, reporting twelve cases treated by this method.[8] This paper included cases of acute amebic dysentery; of chronic amebic dysentery; of acute hepatitis in which the formation of pus was prevented by the use of emetin, and of amebic abscesses of the liver cured by aspiration and injections of emetin.

This was followed by a communication[9] in October, 1912, in which he compared twenty-four cases of amebic dysentery in which soluble salts of emetin were given with thirty consecutive cases in which ipecac was used. Table 1 shows the result:

TABLE 1.—COMPARISON OF IPECAC TREATMENT OF AMEBIC DYSENTERY IN THIRTY CASES WITH EMETIN TREATMENT IN TWENTY-FOUR

	Ipecac	Emetin
Died from dysentery within three days of admission	4	2
Died over three days after admission	7	0
Died from other diseases after cure	0	2
Removed from hospital in bad condition	2	0
Left hospital unchanged or not cured	4	0
Cured	13	20
Average days in hospital of cured patients	16.4	7.2
Average days before stools became normal	11.4	2.35
Grains of ipecac or emetin to that time	406	2

These articles placed the new treatment of amebic dysentery and hepatitis by emetin on a firm basis, and excited world-wide interest. It has since been tried with practically uniform success by French, German, English, American, Italian and Spanish practitioners. The literature summarized in Table 2 includes nearly all of the reported cases up to date, but many more cases have been successfully treated without a report having been made.

It is now believed that sufficient information has been collected with regard to this treatment to warrant a discussion of the following points:

1. Is the emetin treatment really effective in the treatment of amebic dysentery?
